It has been shown that conceptions derive their material from knowledge of perception, and therefore the entire structure of our world of thought rests upon the world of perception. We must therefore be able to go back from every conception, even if only indirectly through intermediate conceptions, to the perceptions from which it is either itself directly derived or those conceptions are derived of which it is again an abstraction. That is to say, we must be able to support it with perceptions which stand to the abstractions in the relation of examples. These perceptions thus afford the real content of all our thought, and whenever they are wanting we have not had conceptions but mere words in our heads. In this respect our intellect is like a bank, which, if it is to be sound, must have cash in its safe, so as to be able to meet all the notes it has issued, in case of demand; the perceptions are the cash, the conceptions are the notes. In this sense the perceptions might very appropriately be called *primary*, and the conceptions, on the other hand, *secondary* ideas. Not quite so aptly, the Schoolmen, following the example of Aristotle (*Metaph.*, vi. 11, xi. 1), called real things *substantiæ primæ*, and the conceptions *substantiæ secundæ*. Books impart only secondary ideas. Mere conceptions of a thing without perception give only a general knowledge of it. We only have a thorough understanding of things and their relations so far as we are able to represent them to ourselves in pure, distinct perceptions, without the aid of words. To explain words by words, to compare concepts with concepts, in which most philosophising consists, is a trivial shifting about of the concept-spheres in order to see which goes into the other and which does not. At the best we can in this way only arrive at conclusions; but even conclusions give no really new knowledge, but only show us all that lay in the knowledge we already possessed, and what part of it perhaps might be applicable to the particular case. On the other hand, to perceive, to allow the things themselves to speak to us, to apprehend new relations of them, and then to take up and deposit all this in conceptions, in order to possess it with certainty — that gives new knowledge. But, while almost every one is capable of comparing conceptions with conceptions, to compare conceptions with perceptions is a gift of the select few. It is the condition,

according to the degree of its perfection, of wit, judgment, ingenuity, genius. The former faculty, on the contrary, results in little more than possibly rational reflections. The inmost kernel of all genuine and actual knowledge is a perception; and every new truth is the profit or gain yielded by a perception. All original thinking takes place in images, and this is why imagination is so necessary an instrument of thought, and minds that lack imagination will never accomplish much, unless it be in mathematics. On the other hand, merely abstract thoughts, which have no kernel of perception, are like cloud-structures, without reality. Even writing and speaking, whether didactic or poetical, has for its final aim to guide the reader to the same concrete knowledge from which the author started; if it has not this aim it is bad. This is why the contemplation and observing of every real thing, as soon as it presents something new to the observer, is more instructive than any reading or hearing. For indeed, if we go to the bottom of the matter, all truth and wisdom, nay, the ultimate secret of things, is contained in each real object, yet certainly only *in concreto*, just as gold lies hidden in the ore; the difficulty is to extract it. From a book, on the contrary, at the best we only receive the truth at second hand, and oftener not at all.

In most books, putting out of account those that are thoroughly bad, the author, when their content is not altogether empirical, has certainly *thought* but not *perceived*; he has written from reflection, not from intuition, and it is this that makes them commonplace and tedious. For what the author has thought could always have been thought by the reader also, if he had taken the same trouble; indeed it consists simply of intelligent thought, full exposition of what is *implicite* contained in the theme. But no actually new knowledge comes in this way into the world; this is only created in the moment of perception, of direct comprehension of a new side of the thing. When, therefore, on the contrary, *sight* has formed the foundation of an author's thought, it is as if he wrote from a land where the reader has never been, for all is fresh and new, because it is drawn directly from the original source of all knowledge. Let me illustrate the distinction here touched upon by a perfectly easy and simple example. Any commonplace writer might easily describe profound contemplation or petrifying astonishment by saying: "He stood like a statue;" but Cervantes says: "Like a clothed statue, for the wind moved his garments" (*Don Quixote*, book vi. ch. 19). It is thus that all great minds have ever *thought in presence of the perception*, and

kept their gaze steadfastly upon it in their thought. We recognise this from this fact, among others, that even the most opposite of them so often agree and coincide in some particular; because they all speak of the same thing which they all had before their eyes, the world, the perceived reality; indeed in a certain degree they all say the same thing, and others never believe them. We recognise it further in the appropriateness and originality of the expression, which is always perfectly adapted to the subject because it has been inspired by perception, in the naivete of the language, the freshness of the imagery, and the impressiveness of the similes, all of which qualities, without exception, distinguish the works of great minds, and, on the contrary, are always wanting in the works of others. Accordingly only commonplace forms of expression and trite figures are at the service of the latter, and they never dare to allow themselves to be natural, under penalty of displaying their vulgarity in all its dreary barrenness; instead of this they are affected mannerists. Hence Buffon says: "*Le style est l'homme même*." If men of commonplace mind write poetry they have certain traditional conventional opinions, passions, noble sentiments, &c., which they have received in the abstract, and attribute to the heroes of their poems, who are in this way reduced to mere personifications of those opinions, and are thus themselves to a certain extent abstractions, and therefore insipid and tiresome. If they philosophise, they have taken in a few wide abstract conceptions, which they turn about in all directions, as if they had to do with algebraical equations, and hope that something will come of it; at the most we see that they have all read the same things. Such a tossing to and fro of abstract conceptions, after the manner of algebraical equations, which is now-a-days called dialectic, does not, like real algebra, afford certain results; for here the conception which is represented by the word is not a fixed and perfectly definite quality, such as are symbolised by the letters in algebra, but is wavering and ambiguous, and capable of extension and contraction. Strictly speaking, all thinking, *i.e.*, combining of abstract conceptions, has at the most the *recollections* of earlier perceptions for its material, and this only indirectly, so far as it constitutes the foundation of all conceptions. Real knowledge, on the contrary, that is, immediate knowledge, is perception alone, new, fresh perception itself. Now the concepts which the reason has framed and the memory has preserved cannot all be present to consciousness at once, but only a very small number of them at a time. On the other hand, the energy with which we

apprehend what is present in perception, in which really all that is essential in all things generally is virtually contained and represented, is apprehended, fills the consciousness in one moment with its whole power. Upon this depends the infinite superiority of genius to learning; they stand to each other as the text of an ancient classic to its commentary. All truth and all wisdom really lies ultimately in perception. But this unfortunately can neither be retained nor communicated. The *objective* conditions of such communication can certainly be presented to others purified and illustrated through plastic and pictorial art, and even much more directly through poetry; but it depends so much upon *subjective* conditions, which are not at the command of every one, and of no one at all times, nay, indeed in the higher degrees of perfection, are only the gift of the favoured few. Only the worst knowledge, abstract, secondary knowledge, the conception, the mere shadow of true knowledge, is unconditionally communicable. If perceptions were communicable, that would be a communication worth the trouble; but at last every one must remain in his own skin and skull, and no one can help another. To enrich the conception from perception is the unceasing endeavour of poetry and philosophy. However, the aims of man are essentially *practical*; and for these it is sufficient that what he has apprehended through perception should leave traces in him, by virtue of which he will recognise it in the next similar case; thus he becomes possessed of worldly wisdom. Thus, as a rule, the man of the world cannot teach his accumulated truth and wisdom, but only make use of it; he rightly comprehends each event as it happens, and determines what is in conformity with it. That books will not take the place of experience nor learning of genius are two kindred phenomena. Their common ground is that the abstract can never take the place of the concrete. Books therefore do not take the place of experience, because *conceptions* always remain *general*, and consequently do not get down to the particular, which, however, is just what has to be dealt with in life; and, besides this, all conceptions are abstracted from what is particular and perceived in experience, and therefore one must have come to know these in order adequately to understand even the general conceptions which the books communicate. Learning cannot take the place of genius, because it also affords merely conceptions, but the knowledge of genius consists in the apprehension of the (Platonic) Ideas of things, and therefore is essentially intuitive. Thus in the first of these phenomena the *objective* condition of

perceptive or intuitive knowledge is wanting; in the second the *subjective*; the former may be attained, the latter cannot.

Wisdom and genius, these two summits of the Parnassus of human knowledge, have their foundation not in the abstract and discursive, but in the perceptive faculty. Wisdom proper is something intuitive, not something abstract. It does not consist in principles and thoughts, which one can carry about ready in his mind, as results of his own research or that of others; but it is the whole manner in which the world presents itself in his mind. This varies so much that on account of it the wise man lives in another world from the fool, and the genius sees another world from the blockhead. That the works of the man of genius immeasurably surpass those of all others arises simply from the fact that the world which he sees, and from which he takes his utterances, is so much clearer, as it were more profoundly worked out, than that in the minds of others, which certainly contains the same objects, but is to the world of the man of genius as the Chinese picture without shading and perspective is to the finished oil-painting. The material is in all minds the same; but the difference lies in the perfection of the form which it assumes in each, upon which the numerous grades of intelligence ultimately depend. These grades thus exist in the root, in the *perceptive* or *intuitive* apprehension, and do not first appear in the abstract. Hence original mental superiority shows itself so easily when the occasion arises, and is at once felt and hated by others.

In practical life the intuitive knowledge of the understanding is able to guide our action and behaviour directly, while the abstract knowledge of the reason can only do so by means of the memory. Hence arises the superiority of intuitive knowledge in all cases which admit of no time for reflection; thus for daily intercourse, in which, just on this account, women excel. Only those who intuitively know the nature of men as they are as a rule, and thus comprehend the individuality of the person before them, will understand how to manage him with certainty and rightly. Another may know by heart all the three hundred maxims of Gracian, but this will not save him from stupid mistakes and misconceptions if he lacks that intuitive knowledge. For all *abstract knowledge* affords us primarily mere general principles and rules; but the particular case is almost never to be carried out exactly according to the rule; then the rule itself has to be presented to us at the right time by the memory, which seldom punctually happens; then the *propositio minor* has to be formed out of the present case, and finally the

conclusion drawn. Before all this is done the opportunity has generally turned its back upon us, and then those excellent principles and rules serve at the most to enable us to measure the magnitude of the error we have committed. Certainly with time we gain in this way experience and practice, which slowly grows to knowledge of the world, and thus, in connection with this, the abstract rules may certainly become fruitful. On the other hand, the *intuitive knowledge*, which always apprehends only the particular, stands in immediate relation to the present case. Rule, case, and application are for it one, and action follows immediately upon it. This explains why in real life the scholar, whose pre-eminence lies in the province of abstract knowledge, is so far surpassed by the man of the world, whose pre-eminence consists in perfect intuitive knowledge, which original disposition conferred on him, and a rich experience has developed. The two kinds of knowledge always stand to each other in the relation of paper money and hard cash; and as there are many cases and circumstances in which the former is to be preferred to the latter, so there are also things and situations for which abstract knowledge is more useful than intuitive. If, for example, it is a conception that in some case guides our action, when it is once grasped it has the advantage of being unalterable, and therefore under its guidance we go to work with perfect certainty and consistency. But this certainty which the conception confers on the subjective side is outweighed by the uncertainty which accompanies it on the objective side. The whole conception may be false and groundless, or the object to be dealt with may not come under it, for it may be either not at all or not altogether of the kind which belongs to it. Now if in the particular case we suddenly become conscious of something of this sort, we are put out altogether; if we do not become conscious of it, the result brings it to light. Therefore Vauvenargue says: "*Personne n'est sujet à plus de fautes, que ceux qui n'agissent que par réflexion*." If, on the contrary, it is direct perception of the objects to be dealt with and their relations that guides our action, we easily hesitate at every step, for the perception is always modifiable, is ambiguous, has inexhaustible details in itself, and shows many sides in succession; we act therefore without full confidence. But the subjective uncertainty is compensated by the objective certainty, for here there is no conception between the object and us, we never lose sight of it; if therefore we only see correctly what we have before us and what we do, we shall hit the mark. Our action then is perfectly sure only when it is guided by a conception the

right ground of which, its completeness, and applicability to the given cause is perfectly certain. Action in accordance with conceptions may pass into pedantry, action in accordance with the perceived impression into levity and folly.

Perception is not only the *source* of all knowledge, but is itself knowledge κατ' εξοχην, is the only unconditionally true, genuine knowledge completely worthy of the name. For it alone imparts *insight* properly so called, it alone is actually assimilated by man, passes into his nature, and can with full reason be called *his*; while the conceptions merely cling to him. In the fourth book we see indeed that true virtue proceeds from knowledge of perception or intuitive knowledge; for only those actions which are directly called forth by this, and therefore are performed purely from the impulse of our own nature, are properly symptoms of our true and unalterable character; not so those which, resulting from reflection and its dogmas, are often extorted from the character, and therefore have no unalterable ground in us. But *wisdom* also, the true view of life, the correct eye, and the searching judgment, proceeds from the way in which the man apprehends the perceptible world, but not from his mere abstract knowledge, *i.e.*, not from abstract conceptions. The basis or ultimate content of every science consists, not in proofs, nor in what is proved, but in the unproved foundation of the proofs, which can finally be apprehended only through perception. So also the basis of the true wisdom and real insight of each man does not consist in conceptions and in abstract rational knowledge, but in what is perceived, and in the degree of acuteness, accuracy, and profundity with which he has apprehended it. He who excels here knows the (Platonic) Ideas of the world and life; every case he has seen represents for him innumerable cases; he always apprehends each being according to its true nature, and his action, like his judgment, corresponds to his insight. By degrees also his countenance assumes the expression of penetration, of true intelligence, and, if it goes far enough, of wisdom. For it is pre-eminence in knowledge of perception alone that stamps its impression upon the features also; while pre-eminence in abstract knowledge cannot do this. In accordance with what has been said, we find in all classes men of intellectual superiority, and often quite without learning. Natural understanding can take the place of almost every degree of culture, but no culture can take the place of natural understanding. The scholar has the advantage of such men in the possession of a wealth of cases

and facts (historical knowledge) and of causal determinations (natural science), all in well-ordered connection, easily surveyed; but yet with all this he has not a more accurate and profound insight into what is truly essential in all these cases, facts, and causations. The unlearned man of acuteness and penetration knows how to dispense with this wealth; we can make use of much; we can do with little. One case in his own experience teaches him more than many a scholar is taught by a thousand cases which he *knows*, but does not, properly speaking, *understand*. For the little knowledge of that unlearned man is living, because every fact that is known to him is supported by accurate and well-apprehended perception, and thus represents for him a thousand similar facts. On the contrary, the much knowledge of the ordinary scholar is *dead*, because even if it does not consist, as is often the case, in mere words, it consists entirely in abstract knowledge. This, however, receives its value only through the *perceptive* knowledge of the individual with which it must connect itself, and which must ultimately realise all the conceptions. If now this perceptive knowledge is very scanty, such a mind is like a bank with liabilities tenfold in excess of its cash reserve, whereby in the end it becomes bankrupt. Therefore, while the right apprehension of the perceptible world has impressed the stamp of insight and wisdom on the brow of many an unlearned man, the face of many a scholar bears no other trace of his much study than that of exhaustion and weariness from excessive and forced straining of the memory in the unnatural accumulation of dead conceptions. Moreover, the insight of such a man is often so puerile, so weak and silly, that we must suppose that the excessive strain upon the faculty of indirect knowledge, which is concerned with abstractions, directly weakens the power of immediate perceptive knowledge, and the natural and clear vision is more and more blinded by the light of books. At any rate the constant streaming in of the thoughts of others must confine and suppress our own, and indeed in the long run paralyse the power of thought if it has not that high degree of elasticity which is able to withstand that unnatural stream. Therefore ceaseless reading and study directly injures the mind — the more so that completeness and constant connection of the system of our own thought and knowledge must pay the penalty if we so often arbitrarily interrupt it in order to gain room for a line of thought entirely strange to us. To banish my own thought in order to make room for that of a book would seem to me like what Shakespeare censures in the tourists of his time, that

they sold their own land to see that of others. Yet the inclination for reading of most scholars is a kind of *fuga vacui*, from the poverty of their own minds, which forcibly draws in the thoughts of others. In order to have thoughts they must read something; just as lifeless bodies are only moved from without; while the man who thinks for himself is like a living body that moves of itself. Indeed it is dangerous to read about a subject before we have thought about it ourselves. For along with the new material the old point of view and treatment of it creeps into the mind, all the more so as laziness and apathy counsel us to accept what has already been thought, and allow it to pass for truth. This now insinuates itself, and henceforward our thought on the subject always takes the accustomed path, like brooks that are guided by ditches; to find a thought of our own, a new thought, is then doubly difficult. This contributes much to the want of originality on the part of scholars. Add to this that they suppose that, like other people, they must divide their time between pleasure and work. Now they regard reading as their work and special calling, and therefore they gorge themselves with it, beyond what they can digest. Then reading no longer plays the part of the mere initiator of thought, but takes its place altogether; for they think of the subject just as long as they are reading about it, thus with the mind of another, not with their own. But when the book is laid aside entirely different things make much more lively claims upon their interest; their private affairs, and then the theatre, card-playing, skittles, the news of the day, and gossip. The man of thought is so because such things have no interest for him. He is interested only in his problems, with which therefore he is always occupied, by himself and without a book. To give ourselves this interest, if we have not got it, is impossible. This is the crucial point. And upon this also depends the fact that the former always speak only of what they have read, while the latter, on the contrary, speaks of what he has thought, and that they are, as Pope says:

"For ever reading, never to be read."

The mind is naturally free, not a slave; only what it does willingly, of its own accord, succeeds. On the other hand, the compulsory exertion of a mind in studies for which it is not qualified, or when it has become tired, or in general too continuously and *invita Minerva*, dulls the brain, just as reading by moonlight dulls the eyes. This is especially the case with the straining of the immature brain in the earlier years of childhood. I believe that the learning of Latin and Greek grammar from the sixth to the twelfth

year lays the foundation of the subsequent stupidity of most scholars. At any rate the mind requires the nourishment of materials from without. All that we eat is not at once incorporated in the organism, but only so much of it as is digested; so that only a small part of it is assimilated, and the remainder passes away; and thus to eat more than we can assimilate is useless and injurious. It is precisely the same with what we read. Only so far as it gives food for thought does it increase our insight and true knowledge. Therefore Heracleitus says: "πολυμαθια νουν ου διδασκει" (*multiscitia non dat intellectum*). It seems, however, to me that learning may be compared to a heavy suit of armour, which certainly makes the strong man quite invincible, but to the weak man is a burden under which he sinks altogether.

The exposition given in our third book of the knowledge of the (Platonic) Ideas, as the highest attainable by man, and at the same time entirely *perceptive or intuitive* knowledge, is a proof that the source of true wisdom does not lie in abstract rational knowledge, but in the clear and profound apprehension of the world in perception. Therefore wise men may live in any age, and those of the past remain wise men for all succeeding generations. Learning, on the contrary, is relative; the learned men of the past are for the most part children as compared with us, and require indulgence.

But to him who studies in order to gain *insight* books and studies are only steps of the ladder by which he climbs to the summit of knowledge. As soon as a round of the ladder has raised him a step, he leaves it behind him. The many, on the other hand, who study in order to fill their memory do not use the rounds of the ladder to mount by, but take them off, and load themselves with them to carry them away, rejoicing at the increasing weight of the burden. They remain always below, because they bear what ought to have borne them.

Upon the truth set forth here, that the kernel of all knowledge is the *perceptive or intuitive* apprehension, depends the true and profound remark of Helvetius, that the really characteristic and original views of which a gifted individual is capable, and the working up, development, and manifold application of which is the material of all his works, even if written much later, can arise in him only up to the thirty-fifth or at the latest the fortieth year of his life, and are really the result of combinations he has made in his early youth. For they are not mere connections of abstract

conceptions, but his own intuitive comprehension of the objective world and the nature of things. Now, that this intuitive apprehension must have completed its work by the age mentioned above depends partly on the fact that by that time the ectypes of all (Platonic) Ideas must have presented themselves to the man, and therefore cannot appear later with the strength of the first impression; partly on this, that the highest energy of brain activity is demanded for this quintessence of all knowledge, for this proof before the letter of the apprehension, and this highest energy of the brain is dependent on the freshness and flexibility of its fibres and the rapidity with which the arterial blood flows to the brain. But this again is at its strongest only as long as the arterial system has a decided predominance over the venous system, which begins to decline after the thirtieth year, until at last, after the forty-second year, the venous system obtains the upper hand, as Cabanis has admirably and instructively explained. Therefore the years between twenty and thirty and the first few years after thirty are for the intellect what May is for the trees; only then do the blossoms appear of which all the later fruits are the development. The world of perception has made its impression, and thereby laid the foundation of all the subsequent thoughts of the individual. He may by reflection make clearer what he has apprehended; he may yet acquire much knowledge as nourishment for the fruit which has once set; he may extend his views, correct his conceptions and judgments, it may be only through endless combinations that he becomes completely master of the materials he has gained; indeed he will generally produce his best works much later, as the greatest heat begins with the decline of the day, but he can no longer hope for new original knowledge from the one living fountain of perception. It is this that Byron feels when he breaks forth into his wonderfully beautiful lament:

“No more — no more — oh! never more on me
The freshness of the heart can fall like dew,
Which out of all the lovely things we see
Extracts emotions beautiful and new,
Hived in our bosoms like the bag o’ the bee:
Think’st thou the honey with those objects grew?
Alas! ’twas not in them, but in thy power
To double even the sweetness of a flower.”

Through all that I have said hitherto I hope I have placed in a clear light the important truth that since all abstract knowledge springs from

knowledge of perception, it obtains its whole value from its relation to the latter, thus from the fact that its conceptions, or the abstractions which they denote, can be realised, *i.e.*, proved, through perceptions; and, moreover, that most depends upon the quality of these perceptions. Conceptions and abstractions which do not ultimately refer to perceptions are like paths in the wood that end without leading out of it. The great value of conceptions lies in the fact that by means of them the original material of knowledge is more easily handled, surveyed, and arranged. But although many kinds of logical and dialectical operations are possible with them, yet no entirely original and new knowledge will result from these; that is to say, no knowledge whose material neither lay already in perception nor was drawn from self-consciousness. This is the true meaning of the doctrine attributed to Aristotle: *Nihil est in intellectu, nisi quod antea fuerit in sensu*. It is also the meaning of the Lockeian philosophy, which made for ever an epoch in philosophy, because it commenced at last the serious discussion of the question as to the origin of our knowledge. It is also principally what the "Critique of Pure Reason" teaches. It also desires that we should not remain at the *conceptions*, but go back to their *source*, thus to *perception*; only with the true and important addition that what holds good of the perception also extends to its subjective conditions, thus to the forms which lie predisposed in the perceiving and thinking brain as its natural functions; although these at least *virtualiter* precede the actual sense-perception, *i.e.*, are *a priori*, and therefore do not depend upon sense-perception, but it upon them. For these forms themselves have indeed no other end, nor service, than to produce the empirical perception on the nerves of sense being excited, as other forms are determined afterwards to construct thoughts in the abstract from the material of perception. The "Critique of Pure Reason" is therefore related to the Lockeian philosophy as the analysis of the infinite to elementary geometry, but is yet throughout to be regarded as the *continuation of the Lockeian philosophy*. The given material of every philosophy is accordingly nothing else than the *empirical consciousness*, which divides itself into the consciousness of one's own self (self-consciousness) and the consciousness of other things (external perception). For this alone is what is immediately and actually given. Every philosophy which, instead of starting from this, takes for its starting-point arbitrarily chosen abstract conceptions, such as, for example, absolute, absolute substance, God, infinity, finitude, absolute identity, being, essence, &c.,

&c., moves in the air without support, and can therefore never lead to a real result. Yet in all ages philosophers have attempted it with such materials; and hence even Kant sometimes, according to the common usage, and more from custom than consistency, defines philosophy as a science of mere conceptions. But such a science would really undertake to extract from the partial ideas (for that is what the abstractions are) what is not to be found in the complete ideas (the perceptions), from which the former were drawn by abstraction. The possibility of the syllogism leads to this mistake, because here the combination of the judgments gives a new result, although more apparent than real, for the syllogism only brings out what already lay in the given judgments; for it is true the conclusion cannot contain more than the premisses. Conceptions are certainly the material of philosophy, but only as marble is the material of the sculptor. It is not to work *out of* them but *in* them; that is to say, it is to deposit its results in them, but not to start from them as what is given. Whoever wishes to see a glaring example of such a false procedure from mere conceptions may look at the "*Institutio Theologica*" of Proclus in order to convince himself of the vanity of that whole method. There abstractions such as "ἐν, πληθος, αγαθον, παραγον και παραγομενον, αυταρκες, αιτιον, κρειττον, κινητον, ακινητον, κινουμενον" (*unum*, *multa*, *bonum*, *producens et productum*, *sibi sufficiens*, *causa*, *melius*, *mobile*, *immobile*, *motum*), &c., are indiscriminately collected, but the perceptions to which alone they owe their origin and content ignored and contemptuously disregarded. A theology is then constructed from these conceptions, but its goal, the θεος, is kept concealed; thus the whole procedure is apparently unprejudiced, as if the reader did not know at the first page, just as well as the author, what it is all to end in. I have already quoted a fragment of this above. This production of Proclus is really quite peculiarly adapted to make clear how utterly useless and illusory such combinations of abstract conceptions are, for we can make of them whatever we will, especially if we further take advantage of the ambiguity of many words, such, for example, as κρειττον. If such an architect of conceptions were present in person we would only have to ask naively where all the things are of which he has so much to tell us, and whence he knows the laws from which he draws his conclusions concerning them. He would then soon be obliged to turn to empirical perception, in which alone the real world exhibits itself, from which those conceptions are drawn. Then we would only have to ask further why he did not honestly

start from the given perception of such a world, so that at every step his assertions could be proved by it, instead of operating with conceptions, which are yet drawn from perception alone, and therefore can have no further validity than that which it imparts to them. But of course this is just his trick. Through such conceptions, in which, by virtue of abstraction, what is inseparable is thought as separate, and what cannot be united as united, he goes far beyond the perception which was their source, and thus beyond the limits of their applicability, to an entirely different world from that which supplied the material for building, but just on this account to a world of chimeras. I have here referred to Proclus because in him this procedure becomes specially clear through the frank audacity with which he carries it out. But in Plato also we find some examples of this kind, though not so glaring; and in general the philosophical literature of all ages affords a multitude of instances of the same thing. That of our own time is rich in them. Consider, for example, the writings of the school of Schelling, and observe the constructions that are built up out of abstractions like finite and infinite — being, non-being, other being — activity, hindrance, product — determining, being determined, determinateness — limit, limiting, being limited — unity, plurality, multiplicity — identity, diversity, indifference — thinking, being, essence, &c. Not only does all that has been said above hold good of constructions out of such materials, but because an infinite amount can be thought *through* such wide abstractions, only very little indeed can be thought *in* them; they are empty husks. But thus the matter of the whole philosophising becomes astonishingly trifling and paltry, and hence arises that unutterable and excruciating tediousness which is characteristic of all such writings. If indeed I now chose to call to mind the way in which Hegel and his companions have abused such wide and empty abstractions, I should have to fear that both the reader and I myself would be ill; for the most nauseous tediousness hangs over the empty word-juggling of this loathsome philophaster.

That in *practical* philosophy also no wisdom is brought to light from mere abstract conceptions is the one thing to be learnt from the ethical dissertations of the theologian Schleiermacher, with the delivery of which he has wearied the Berlin Academy for a number of years, and which are shortly to appear in a collected form. In them only abstract conceptions, such as duty, virtue, highest good, moral law, &c., are taken as the starting-point, without further introduction than that they commonly occur in ethical

systems, and are now treated as given realities. He then discusses these from all sides with great subtilty, but, on the other hand, never makes for the source of these conceptions, for the thing itself, the actual human life, to which alone they are related, from which they ought to be drawn, and with which morality has, properly speaking, to do. On this account these diatribes are just as unfruitful and useless as they are tedious, which is saying a great deal. At all times we find persons, like this theologian, who is too fond of philosophising, famous while they are alive, afterwards soon forgotten. My advice is rather to read those whose fate has been the opposite of this, for time is short and valuable.

Now although, in accordance with all that has been said, wide, abstract conceptions, which can be realised in no perception, must never be the source of knowledge, the starting-point or the proper material of philosophy, yet sometimes particular results of philosophy are such as can only be thought in the abstract, and cannot be proved by any perception. Knowledge of this kind will certainly only be half knowledge; it will, as it were, only point out the place where what is to be known lies; but this remains concealed. Therefore we should only be satisfied with such conceptions in the most extreme case, and when we have reached the limit of the knowledge possible to our faculties. An example of this might perhaps be the conception of a being out of time; such as the proposition: the indestructibility of our true being by death is not a continued existence of it. With conceptions of this sort the firm ground which supports our whole knowledge, the perceptible, seems to waver. Therefore philosophy may certainly at times, and in case of necessity, extend to such knowledge, but it must never begin with it.

The working with wide abstractions, which is condemned above, to the entire neglect of the perceptive knowledge from which they are drawn, and which is therefore their permanent and natural controller, was at all times the principal source of the errors of dogmatic philosophy. A science constructed from the mere comparison of conceptions, that is, from general principles, could only be certain if all its principles were synthetical *a priori*, as is the case in mathematics: for only such admit of no exceptions. If, on the other hand, the principles have any empirical content, we must keep this constantly at hand, to control the general principles. For no truths which are in any way drawn from experience are ever unconditionally true. They have therefore only an approximately universal validity; for here there

is no rule without an exception. If now I link these principles together by means of the intersection of their concept-spheres, one conception might very easily touch the other precisely where the exception lies. But if this happens even only once in the course of a long train of reasoning, the whole structure is loosed from its foundation and moves in the air. If, for example, I say, "The ruminants have no front incisors," and apply this and what follows from it to the camel, it all becomes false, for it only holds good of horned ruminants. What Kant calls *das Vernünfteln*, mere abstract reasoning, and so often condemns, is just of this sort. For it consists simply in subsuming conceptions under conceptions, without reference to their origin, and without proof of the correctness and exclusiveness of such subsumption — a method whereby we can arrive by longer or shorter circuits at almost any result we choose to set before us as our goal. Hence this mere abstract reasoning differs only in degree from sophistication strictly so called. But sophistication is in the theoretical sphere exactly what chicanery is in the practical. Yet even Plato himself has very frequently permitted such mere abstract reasoning; and Proclus, as we have already mentioned, has, after the manner of all imitators, carried this fault of his model much further. Dionysius the Areopagite, "*De Divinis Nominibus*," is also strongly affected with this. But even in the fragments of the Eleatic Melissus we already find distinct examples of such mere abstract reasoning (especially § 2-5 in Brandis' *Comment. Eleat.*) His procedure with the conceptions, which never touch the reality from which they have their content, but, moving in the atmosphere of abstract universality, pass away beyond it, resembles blows which never hit the mark. A good pattern of such mere abstract reasoning is the "*De Diis et Mundo*" of the philosopher Sallustius Büchelchen; especially chaps. 7, 12, and 17. But a perfect gem of philosophical mere abstract reasoning passing into decided sophistication is the following reasoning of the Platonist, Maximus of Tyre, which I shall quote, as it is short: "Every injustice is the taking away of a good. There is no other good than virtue: but virtue cannot be taken away: thus it is not possible that the virtuous can suffer injustice from the wicked. It now remains either that no injustice can be suffered, or that it is suffered by the wicked from the wicked. But the wicked man possesses no good at all, for only virtue is a good; therefore none can be taken from him. Thus he also can suffer no injustice. Thus injustice is an impossible thing." The original, which is less concise through repetitions, runs thus: "Αδικια εστι αφαιρεσις

αγαθου; το δε αγαθον τι αν ειη αλλο η αρετη? — ἡ δε αρετη αναφαιρετον. Ουκ αδικησεται τοινυν ὁ την αρετην εχων, η ουκ εστιν αδικια αφαιρεσις αγαθου; ουδεν γαρ αγαθον αφαιρετον, ουδ᾽ χαποβλητον, ουδ ἑλετον, ουδε ληιστον. Ειεν ουν, ουδ᾽ αδικειται ὁ χρηστος, ουδ ὑπο του μοχθηρου; αναφαιρετος γαρ. Λειπεται τοινυν η μηδενα αδικεισθαι καθαπαξ, η τον μοχθηρον ὑπο του ὁμοιου; αλλα τῳ μοχθηρῳ ουδενος μετεστιν αγαθου; ἡ δε αδικια ην αγαθου αφαιρεσις; ὁ δε μη εχων ὁ, τι αφαιρεσθη, ουδε εις ὁ, τι αδικησθη, εχει" (*Sermo 2*). I shall add further a modern example of such proofs from abstract conceptions, by means of which an obviously absurd proposition is set up as the truth, and I shall take it from the works of a great man, Giordano Bruno. In his book, "*Del Infinito Universo e Mondi*" (p. 87 of the edition of A. Wagner), he makes an Aristotelian prove (with the assistance and exaggeration of the passage of Aristotle's *De Cœlo*, i. 5) that there can be *no space* beyond the world. The world is enclosed by the eight spheres of Aristotle, and beyond these there can be no space. For if beyond these there were still a body, it must either be simple or compound. It is now proved sophistically, from principles which are obviously begged, that no *simple* body could be there; and therefore, also, no compound body, for it would necessarily be composed of simple ones. Thus in general there can be no body there — but if not, then *no space*. For space is defined as "that in which bodies can be;" and it has just been proved that no body can be there. Thus there is also there no space. This last is the final stroke of this proof from abstract conceptions. It ultimately rests on the fact that the proposition, "Where no space is, there can be no body" is taken as a universal negative, and therefore converted simply, "Where no body can be there is no space." But the former proposition, when properly regarded, is a universal affirmative: "Everything that has no space has no body," thus it must not be converted simply. Yet it is not every proof from abstract conceptions, with a conclusion which clearly contradicts perception (as here the finiteness of space), that can thus be referred to a logical error. For the sophistry does not always lie in the form, but often in the matter, in the premisses, and in the indefiniteness of the conceptions and their extension. We find numerous examples of this in Spinoza, whose method indeed it is to prove from conceptions. See, for example, the miserable sophisms in his "Ethics," P. iv., prop. 29-31, by means of the ambiguity of the uncertain conceptions *convenire* and *commune habere*. Yet this does not prevent the neo-Spinozists of our own day from taking all that he has said for gospel.

Of these the Hegelians, of whom there are actually still a few, are specially amusing on account of their traditional reverence for his principle, *omnis determinatio est negatio*, at which, according to the charlatan spirit of the school, they put on a face as if it was able to unhinge the world; whereas it is of no use at all, for even the simplest can see for himself that if I limit anything by determinations, I thereby exclude and thus negate what lies beyond these limits.

Thus in all mere reasonings of the above kind it becomes very apparent what errors that algebra with mere conceptions, uncontrolled by perception, is exposed to, and that therefore perception is for our intellect what the firm ground upon which it stands is for our body: if we forsake perception everything is *instabilis tellus, innabilis unda*. The reader will pardon the fulness of these expositions and examples on account of their instructiveness. I have sought by means of them to bring forward and support the difference, indeed the opposition, between perceptive and abstract or reflected knowledge, which has hitherto been too little regarded, and the establishment of which is a fundamental characteristic of my philosophy. For many phenomena of our mental life are only explicable through this distinction. The connecting link between these two such different kinds of knowledge is the *faculty of judgment*, as I have shown in § 14 of the first volume. This faculty is certainly also active in the province of mere abstract knowledge, in which it compares conceptions only with conceptions; therefore every judgment, in the logical sense of the word, is certainly a work of the faculty of judgment, for it always consists in the subsumption of a narrower conception under a wider one. Yet this activity of the faculty of judgment, in which it merely compares conceptions with each other, is a simpler and easier task than when it makes the transition from what is quite particular, the perception, to the essentially general, the conception. For by the analysis of conceptions into their essential predicates it must be possible to decide upon purely logical grounds whether they are capable of being united or not, and for this the mere reason which every one possesses is sufficient. The faculty of judgment is therefore only active here in shortening this process, for he who is gifted with it sees at a glance what others only arrive at through a series of reflections. But its activity in the narrower sense really only appears when what is known through perception, thus the real experience, has to be carried over into distinct abstract knowledge, subsumed under accurately corresponding conceptions, and

thus translated into reflected rational knowledge. It is therefore this faculty which has to establish the firm *basis* of all sciences, which always consists of what is known directly and cannot be further denied. Therefore here, in the fundamental judgments, lies the difficulty of the sciences, not in the inferences from these. To infer is easy, to judge is difficult. False inferences are rare, false judgments are always the order of the day. Not less in practical life has the faculty of judgment to give the decision in all fundamental conclusions and important determinations. Its office is in the main like that of the judicial sentence. As the burning-glass brings to a focus all the sun's rays, so when the understanding works, the intellect has to bring together all the data which it has upon the subject so closely that the understanding comprehends them at a glance, which it now rightly fixes, and then carefully makes the result distinct to itself. Further, the great difficulty of judging in most cases depends upon the fact that we have to proceed from the consequent to the reason, a path which is always uncertain; indeed I have shown that the source of all error lies here. Yet in all the empirical sciences, and also in the affairs of real life, this way is for the most part the only one open to us. The experiment is an attempt to go over it again the other way; therefore it is decisive, and at least brings out error clearly; provided always that it is rightly chosen and honestly carried out; not like Newton's experiments in connection with the theory of colours. But the experiment itself must also again be judged. The complete certainty of the *a priori* sciences, logic and mathematics, depends principally upon the fact that in them the path from the reason to the consequent is open to us, and it is always certain. This gives them the character of *purely objective* sciences, *i.e.*, sciences with regard to whose truths all who understand them must judge alike; and this is all the more remarkable as they are the very sciences which rest on the subjective forms of the intellect, while the empirical sciences alone have to do with what is palpably objective.

Wit and ingenuity are also manifestations of the faculty of judgment; in the former its activity is reflective, in the latter subsuming. In most men the faculty of judgment is only nominally present; it is a kind of irony that it is reckoned with the normal faculties of the mind, instead of being only attributed to the *monstris per excessum*. Ordinary men show even in the smallest affairs want of confidence in their own judgment, just because they know from experience that it is of no service. With them prejudice and imitation take its place; and thus they are kept in a state of continual non-

age, from which scarcely one in many hundreds is delivered. Certainly this is not avowed, for even to themselves they appear to judge; but all the time they are glancing stealthily at the opinion of others, which is their secret standard. While each one would be ashamed to go about in a borrowed coat, hat, or mantle, they all have nothing but borrowed opinions, which they eagerly collect wherever they can find them, and then strut about giving them out as their own. Others borrow them again from them and do the same thing. This explains the rapid and wide spread of errors, and also the fame of what is bad; for the professional purveyors of opinion, such as journalists and the like, give as a rule only false wares, as those who hire out masquerading dresses give only false jewels.

Chapter VIII.[20] On The Theory Of The Ludicrous.

My theory of the ludicrous also depends upon the opposition explained in the preceding chapters between perceptible and abstract ideas, which I have brought into such marked prominence. Therefore what has still to be said in explanation of this theory finds its proper place here, although according to the order of the text it would have to come later.

The problem of the origin, which is everywhere the same, and hence of the peculiar significance of laughter, was already known to Cicero, but only to be at once dismissed as insoluble (*De Orat.*, ii. 58). The oldest attempt known to me at a psychological explanation of laughter is to be found in Hutcheson's "Introduction into Moral Philosophy," Bk. I., ch. i. § 14. A somewhat later anonymous work, "*Traité des Causes Physiques et Morals du Rire*," 1768, is not without merit as a ventilation of the subject. Platner, in his "Anthropology," § 894, has collected the opinions of the philosophers from Hume to Kant who have attempted an explanation of this phenomenon peculiar to human nature. Kant's and Jean Paul's theories of the ludicrous are well known. I regard it as unnecessary to prove their incorrectness, for whoever tries to refer given cases of the ludicrous to them will in the great majority of instances be at once convinced of their insufficiency.

According to my explanation given in the first volume, the source of the ludicrous is always the paradoxical, and therefore unexpected, subsumption of an object under a conception which in other respects is different from it, and accordingly the phenomenon of laughter always signifies the sudden apprehension of an incongruity between such a conception and the real object thought under it, thus between the abstract and the concrete object of perception. The greater and more unexpected, in the apprehension of the laughter, this incongruity is, the more violent will be his laughter. Therefore in everything that excites laughter it must always be possible to show a conception and a particular, that is, a thing or event, which certainly can be subsumed under that conception, and therefore thought through it, yet in another and more predominating aspect does not belong to it at all, but is strikingly different from everything else that is thought through that conception. If, as often occurs, especially in witticisms, instead of such a real object of perception, the conception of a subordinate species is brought under the higher conception of the genus, it will yet excite laughter only

through the fact that the imagination realises it, *i.e.*, makes a perceptible representative stand for it, and thus the conflict between what is thought and what is perceived takes place. Indeed if we wish to understand this perfectly explicitly, it is possible to trace everything ludicrous to a syllogism in the first figure, with an undisputed *major* and an unexpected *minor*, which to a certain extent is only sophistically valid, in consequence of which connection the conclusion partakes of the quality of the ludicrous.

In the first volume I regarded it as superfluous to illustrate this theory by examples, for every one can do this for himself by a little reflection upon cases of the ludicrous which he remembers. Yet, in order to come to the assistance of the mental inertness of those readers who prefer always to remain in a passive condition, I will accommodate myself to them. Indeed in this third edition I wish to multiply and accumulate examples, so that it may be indisputable that here, after so many fruitless earlier attempts, the true theory of the ludicrous is given, and the problem which was proposed and also given up by Cicero is definitely solved.

If we consider that an angle requires two lines meeting so that if they are produced they will intersect each other; on the other hand, that the tangent of a circle only touches it at one point, but at this point is really parallel to it; and accordingly have present to our minds the abstract conviction of the impossibility of an angle between the circumference of a circle and its tangent; and if now such an angle lies visibly before us upon paper, this will easily excite a smile. The ludicrousness in this case is exceedingly weak; but yet the source of it in the incongruity of what is thought and perceived appears in it with exceptional distinctness. When we discover such an incongruity, the occasion for laughter that thereby arises is, according as we pass from the real, *i.e.*, the perceptible, to the conception, or conversely from the conception to the real, either a witticism or an absurdity, which in a higher degree, and especially in the practical sphere, is folly, as was explained in the text. Now to consider examples of the first case, thus of wit, we shall first of all take the familiar anecdote of the Gascon at whom the king laughed when he saw him in light summer clothing in the depth of winter, and who thereupon said to the king: “If your Majesty had put on what I have, you would find it very warm;” and on being asked what he had put on, replied: “My whole wardrobe!” Under this last conception we have to think both the unlimited wardrobe of a king and the single summer coat of a poor devil, the sight of which upon his freezing body shows its great

incongruity with the conception. The audience in a theatre in Paris once called for the "Marseillaise" to be played, and as this was not done, began shrieking and howling, so that at last a commissary of police in uniform came upon the stage and explained that it was not allowed that anything should be given in the theatre except what was in the playbill. Upon this a voice cried: "*Et vous, Monsieur, êtes-vous aussi sur l'affiche?*" — a hit which was received with universal laughter. For here the subsumption of what is heterogeneous is at once distinct and unforced. The epigramme:

"Bav is the true shepherd of whom the Bible spake:

Though his flock be all asleep, he alone remains awake:"

subsumes, under the conception of a sleeping flock and a waking shepherd, the tedious preacher who still bellows on unheard when he has sent all the people to sleep. Analogous to this is the epitaph on a doctor: "Here lies he like a hero, and those he has slain lie around him;" it subsumes under the conception, honourable to the hero, of "lying surrounded by dead bodies," the doctor, who is supposed to preserve life. Very commonly the witticism consists in a single expression, through which only the conception is given, under which the case presented can be subsumed, though it is very different from everything else that is thought under it. So is it in "Romeo" when the vivacious Mercutio answers his friends who promise to visit him on the morrow: "Ask for me to-morrow, and you shall find me a grave man." Under this conception a dead man is here subsumed; but in English there is also a play upon the words, for "a grave man" means both a serious man and a man of the grave. Of this kind is also the well-known anecdote of the actor Unzelmann. In the Berlin theatre he was strictly forbidden to improvise. Soon afterwards he had to appear on the stage on horseback, and just as he came on the stage the horse dunged, at which the audience began to laugh, but laughed much more when Unzelmann said to the horse: "What are you doing? Don't you know we are forbidden to improvise?" Here the subsumption of the heterogeneous under the more general conception is very distinct, but the witticism is exceedingly happy, and the ludicrous effect produced by it excessively strong. To this class also belongs the following announcement from Hall in a newspaper of March 1851: "The band of Jewish swindlers to which we have referred were again delivered over to us with obligato accompaniment." This subsuming of a police escort under a musical term is very happy, though it approaches the mere play upon words. On the other

hand, it is exactly a case of the kind we are considering when Saphir, in a paper-war with the actor Angeli, describes him as "Angeli, who is equally great in mind and body." The small statue of the actor was known to the whole town, and thus under the conception "great" unusual smallness was presented to the mind. Also when the same Saphir calls the airs of a new opera "good old friends," and so brings the quality which is most to be condemned under a conception which is usually employed to commend. Also, if we should say of a lady whose favour could be influenced by presents, that she knew how to combine the *utile* with the *dulci*. For here we bring the moral life under the conception of a rule which Horace has recommended in an æsthetical reference. Also if to signify a brothel we should call it the "modest abode of quiet joys." Good society, in order to be thoroughly insipid, has forbidden all decided utterances, and therefore all strong expressions. Therefore it is wont, when it has to signify scandalous or in any way indecent things, to mitigate or extenuate them by expressing them through general conceptions. But in this way it happens that they are more or less incongruously subsumed, and in a corresponding degree the effect of the ludicrous is produced. To this class belongs the use of *utile dulci* referred to above, and also such expressions as the following: "He had unpleasantness at the ball" when he was thrashed and kicked out; or, "He has done too well" when he is drunk; and also, "The woman has weak moments" if she is unfaithful to her husband, &c. Equivocal sayings also belong to the same class. They are conceptions which in themselves contain nothing improper, but yet the case brought under them leads to an improper idea. They are very common in society. But a perfect example of a full and magnificent equivocation is Shenstone's incomparable epitaph on a justice of the peace, which, in its high-flown lapidary style, seems to speak of noble and sublime things, while under each of their conceptions something quite different is to be subsumed, which only appears in the very last word as the unexpected key to the whole, and the reader discovers with loud laughter that he has only read a very obscene equivocation. In this smooth-combed age it is altogether impossible to quote this here, not to speak of translating it; it will be found in Shenstone's poetical works, under the title "Inscription." Equivocations sometimes pass over into mere puns, about which all that is necessary has been said in the text.

Further, the ultimate subsumption, ludicrous to all, of what in one respect is heterogeneous, under a conception which in other respects agrees with it,

may take place contrary to our intention. For example, one of the free negroes in North America, who take pains to imitate the whites in everything, quite recently placed an epitaph over his dead child which begins, “Lovely, early broken lily.” If, on the contrary, something real and perceptible is, with direct intention, brought under the conception of its opposite, the result is plain, common irony. For example, if when it is raining hard we say, “Nice weather we are having to-day;” or if we say of an ugly bride, “That man has found a charming treasure;” or of a knave, “This honest man,” &c. &c. Only children and quite uneducated people will laugh at such things; for here the incongruity between what is thought and what is perceived is total. Yet just in this direct exaggeration in the production of the ludicrous its fundamental character, incongruity, appears very distinctly. This species of the ludicrous is, on account of its exaggeration and distinct intention, in some respects related to *parody*. The procedure of the latter consists in this. It substitutes for the incidents and words of a serious poem or drama insignificant low persons or trifling motives and actions. It thus subsumes the commonplace realities which it sets forth under the lofty conceptions given in the theme, under which in a certain respect they must come, while in other respects they are very incongruous; and thereby the contrast between what is perceived and what is thought appears very glaring. There is no lack of familiar examples of this, and therefore I shall only give one, from the “Zobeide” of Carlo Gozzi, act iv., scene 3, where the famous stanza of Ariosto (*Orl. Fur.*, i. 22), “*Oh gran bontà de’ cavalieri antichi*,” &c., is put word for word into the mouth of two clowns who have just been thrashing each other, and tired with this, lie quietly side by side. This is also the nature of the application so popular in Germany of serious verses, especially of Schiller, to trivial events, which clearly contains a subsumption of heterogeneous things under the general conception which the verse expresses. Thus, for example, when any one has displayed a very characteristic trait, there will rarely be wanting some one to say, “From that I know with whom I have to do.” But it was original and very witty of a man who was in love with a young bride to quote to the newly married couple (I know not how loudly) the concluding words of Schiller’s ballad, “The Surety:”

“Let me be, I pray you,
In your bond the third.”

The effect of the ludicrous is here strong and inevitable, because under the conceptions through which Schiller presents to the mind a moral and noble relation, a forbidden and immoral relation is subsumed, and yet correctly and without change, thus is thought through it. In all the examples of wit given here we find that under a conception, or in general an abstract thought, a real thing is, directly, or by means of a narrower conception, subsumed, which indeed, strictly speaking, comes under it, and yet is as different as possible from the proper and original intention and tendency of the thought. Accordingly wit, as a mental capacity, consists entirely in a facility for finding for every object that appears a conception under which it certainly can be thought, though it is very different from all the other objects which come under this conception.

The second species of the ludicrous follows, as we have mentioned, the opposite path from the abstract conception to the real or perceptible things thought through it. But this now brings to light any incongruity with the conception which was overlooked, and hence arises an absurdity, and therefore in the practical sphere a foolish action. Since the play requires action, this species of the ludicrous is essential to comedy. Upon this depends the observation of Voltaire: "*J'ai cru remarquer aux spectacles, qu'il ne s'élève presque jamais de ces éclats de rire universels, qu'à l'occasion d'une* méprise" (*Preface de L'Enfant Prodigue*). The following may serve as examples of this species of the ludicrous. When some one had declared that he was fond of walking alone, an Austrian said to him: "You like walking alone; so do I: therefore we can go together." He starts from the conception, "A pleasure which two love they can enjoy in common," and subsumes under it the very case which excludes community. Further, the servant who rubbed a worn sealskin in his master's box with Macassar oil, so that it might become covered with hair again; in doing which he started from the conception, "Macassar oil makes hair grow." The soldiers in the guard-room who allowed a prisoner who was brought in to join in their game of cards, then quarrelled with him for cheating, and turned him out. They let themselves be led by the general conception, "Bad companions are turned out," and forget that he is also a prisoner, *i.e.*, one whom they ought to hold fast. Two young peasants had loaded their gun with coarse shot, which they wished to extract, in order to substitute fine, without losing the powder. So one of them put the mouth of the barrel in his hat, which he took between his legs, and said to the other: "Now you pull

the trigger slowly, slowly, slowly; then the shot will come first.” He starts from the conception, “Prolonging the cause prolongs the effect.” Most of the actions of Don Quixote are also cases in point, for he subsumes the realities he encounters under conceptions drawn from the romances of chivalry, from which they are very different. For example, in order to support the oppressed he frees the galley slaves. Properly all Münchhausenisms are also of this nature, only they are not actions which are performed, but impossibilities, which are passed off upon the hearer as having really happened. In them the fact is always so conceived that when it is thought merely in the abstract, and therefore comparatively *a priori*, it appears possible and plausible; but afterwards, if we come down to the perception of the particular case, thus *a posteriori* the impossibility of the thing, indeed the absurdity of the assumption, is brought into prominence, and excites laughter through the evident incongruity of what is perceived and what is thought. For example, when the melodies frozen up in the post-horn are thawed in the warm room — when Münchhausen, sitting upon a tree during a hard frost, draws up his knife which has dropped to the ground by the frozen jet of his own water, &c. Such is also the story of the two lions who broke down the partition between them during the night and devoured each other in their rage, so that in the morning there was nothing to be found but the two tails.

There are also cases of the ludicrous where the conception under which the perceptible facts are brought does not require to be expressed or signified, but comes into consciousness itself through the association of ideas. The laughter into which Garrick burst in the middle of playing tragedy because a butcher in the front of the pit, who had taken off his wig to wipe the sweat from his head, placed the wig for a while upon his large dog, who stood facing the stage with his fore paws resting on the pit railings, was occasioned by the fact that Garrick started from the conception of a spectator, which was added in his own mind. This is the reason why certain animal forms, such as apes, kangaroos, jumping-hares, &c., sometimes appear to us ludicrous because something about them resembling man leads us to subsume them under the conception of the human form, and starting from this we perceive their incongruity with it.

Now the conceptions whose observed incongruity with the perceptions moves us to laughter are either those of others or our own. In the first case we laugh at others, in the second we feel a surprise, often agreeable, at the

least amusing. Therefore children and uneducated people laugh at the most trifling things, even at misfortunes, if they were unexpected, and thus convicted their preconceived conception of error. As a rule laughing is a pleasant condition; accordingly the apprehension of the incongruity between what is thought and what is perceived, that is, the real, gives us pleasure, and we give ourselves up gladly to the spasmodic convulsions which this apprehension excites. The reason of this is as follows. In every suddenly appearing conflict between what is perceived and what is thought, what is perceived is always unquestionably right; for it is not subject to error at all, requires no confirmation from without, but answers for itself. Its conflict with what is thought springs ultimately from the fact that the latter, with its abstract conceptions, cannot get down to the infinite multifariousness and fine shades of difference of the concrete. This victory of knowledge of perception over thought affords us pleasure. For perception is the original kind of knowledge inseparable from animal nature, in which everything that gives direct satisfaction to the will presents itself. It is the medium of the present, of enjoyment and gaiety; moreover it is attended with no exertion. With thinking the opposite is the case; it is the second power of knowledge, the exercise of which always demands some, and often considerable, exertion. Besides, it is the conceptions of thought that often oppose the gratification of our immediate desires, for, as the medium of the past, the future, and of seriousness, they are the vehicle of our fears, our repentance, and all our cares. It must therefore be diverting to us to see this strict, untiring, troublesome governess, the reason, for once convicted of insufficiency. On this account then the mien or appearance of laughter is very closely related to that of joy.

On account of the want of reason, thus of general conceptions, the brute is incapable of laughter, as of speech. This is therefore a prerogative and characteristic mark of man. Yet it may be remarked in passing that his one friend the dog has an analogous characteristic action peculiar to him alone in distinction from all other brutes, the very expressive, kindly, and thoroughly honest fawning and wagging of its tail. But how favourably does this salutation given him by nature compare with the bows and simpering civilities of men. At least for the present, it is a thousand times more reliable than their assurance of inward friendship and devotion.

The opposite of laughing and joking is *seriousness*. Accordingly it consists in the consciousness of the perfect agreement and congruity of the

conception, or thought, with what is perceived, or the reality. The serious man is convinced that he thinks the things as they are, and that they are as he thinks them. This is just why the transition from profound seriousness to laughter is so easy, and can be effected by trifles. For the more perfect that agreement assumed by seriousness may seem to be, the more easily is it destroyed by the unexpected discovery of even a slight incongruity. Therefore the more a man is capable of entire seriousness, the more heartily can he laugh. Men whose laughter is always affected and forced are intellectually and morally of little worth; and in general the way of laughing, and, on the other hand, the occasions of it, are very characteristic of the person. That the relations of the sexes afford the easiest materials for jokes always ready to hand and within the reach of the weakest wit, as is proved by the abundance of obscene jests, could not be if it were not that the deepest seriousness lies at their foundation.

That the laughter of others at what we do or say seriously offends us so keenly depends on the fact that it asserts that there is a great incongruity between our conceptions and the objective realities. For the same reason, the predicate "ludicrous" or "absurd" is insulting. The laugh of scorn announces with triumph to the baffled adversary how incongruous were the conceptions he cherished with the reality which is now revealing itself to him. Our own bitter laughter at the fearful disclosure of the truth through which our firmly cherished expectations are proved to be delusive is the active expression of the discovery now made of the incongruity between the thoughts which, in our foolish confidence in man or fate, we entertained, and the truth which is now unveiled.

The *intentionally* ludicrous is the *joke*. It is the effort to bring about a discrepancy between the conceptions of another and the reality by disarranging one of the two; while its opposite, *seriousness*, consists in the exact conformity of the two to each other, which is at least aimed at. But if now the joke is concealed behind seriousness, then we have *irony*. For example, if with apparent seriousness we acquiesce in the opinions of another which are the opposite of our own, and pretend to share them with him, till at last the result perplexes him both as to us and them. This is the attitude of Socrates as opposed to Hippias, Protagoras, Gorgias, and other sophists, and indeed often to his collocutors in general. The converse of irony is accordingly seriousness concealed behind a joke, and this is *humour*. It might be called the double counterpoint of irony. Explanations

such as “Humour is the interpenetration of the finite and the infinite” express nothing more than the entire incapacity for thought of those who are satisfied with such empty phrases. Irony is objective, that is, intended for another; but humour is subjective, that is, it primarily exists only for one’s own self. Accordingly we find the masterpieces of irony among the ancients, but those of humour among the moderns. For, more closely considered, humour depends upon a subjective, yet serious and sublime mood, which is involuntarily in conflict with a common external world very different from itself, which it cannot escape from and to which it will not give itself up; therefore, as an accommodation, it tries to think its own point of view and that external world through the same conceptions, and thus a double incongruity arises, sometimes on the one side, sometimes on the other, between these concepts and the realities thought through them. Hence the impression of the intentionally ludicrous, thus of the joke, is produced, behind which, however, the deepest seriousness is concealed and shines through. Irony begins with a serious air and ends with a smile; with humour the order is reversed. The words of Mercutio quoted above may serve as an example of humour. Also in “Hamlet” — *Polonius*: “My honourable lord, I will most humbly take my leave of you. *Hamlet*: You cannot, sir, take from me anything that I will more willingly part withal, except my life, except my life, except my life.” Again, before the introduction of the play at court, Hamlet says to Ophelia: “What should a man do but be merry? for, look you, how cheerfully my mother looks, and my father died within these two hours. *Ophelia*: Nay, ’tis twice two months, my lord. *Hamlet*: So long? Nay, then let the devil wear black, for I’ll have a suit of sables.”

Again, in Jean Paul’s “Titan,” when Schoppe, melancholy and now brooding over himself, frequently looking at his hands, says to himself, “There sits a lord in bodily reality, and I in him; but who is such?” Heinrich Heine appears as a true humourist in his “*Romancero*.” Behind all his jokes and drollery we discern a profound seriousness, which is ashamed to appear unveiled. Accordingly humour depends upon a special kind of mood or temper (German, *Laune*, probably from *Luna*) through which conception in all its modifications, a decided predominance of the subjective over the objective in the apprehension of the external world, is thought. Moreover, every poetical or artistic presentation of a comical, or indeed even a farcical scene, through which a serious thought yet glimmers as its concealed

background, is a production of humour, thus is humorous. Such, for example, is a coloured drawing of Tischbein's, which represents an empty room, lighted only by the blazing fire in the grate. Before the fire stands a man with his coat off, in such a position that his shadow, going out from his feet, stretches across the whole room. Tischbein comments thus on the drawing: "This is a man who has succeeded in nothing in the world, and who has made nothing of it; now he rejoices that he can throw such a large shadow." Now, if I had to express the seriousness that lies concealed behind this jest, I could best do so by means of the following verse taken from the Persian poem of Anwari Soheili: —

"If thou hast lost possession of a world,
Be not distressed, for it is nought;
Or hast thou gained possession of a world,
Be not o'erjoyed, for it is nought.
Our pains, our gains, all pass away;
Get thee beyond the world, for it is nought."

That at the present day the word humorous is generally used in German literature in the sense of comical arises from the miserable desire to give things a more distinguished name than belongs to them, the name of a class that stands above them. Thus every inn must be called a hotel, every money-changer a banker, every concert a musical academy, the merchant's counting-house a bureau, the potter an artist in clay, and therefore also every clown a humourist. The word *humour* is borrowed from the English to denote a quite peculiar species of the ludicrous, which indeed, as was said above, is related to the sublime, and which was first remarked by them. But it is not intended to be used as the title for all kinds of jokes and buffoonery, as is now universally the case in Germany, without opposition from men of letters and scholars; for the true conception of that modification, that tendency of the mind, that child of the sublime and the ridiculous, would be too subtle and too high for their public, to please which they take pains to make everything flat and vulgar. Well, "high words and a low meaning" is in general the motto of the noble present, and accordingly now-a-days he is called a humourist who was formerly, called a buffoon.

Chapter IX.[21] On Logic In General.

Logic, Dialectic, and Rhetoric go together, because they make up the whole of a *technic of reason*, and under this title they ought also to be taught — Logic as the technic of our own thinking, Dialectic of disputing with others, and Rhetoric of speaking to many (*concionatio*); thus corresponding to the singular, dual, and plural, and to the monologue, the dialogue, and the panegyric.

Under Dialectic I understand, in agreement with Aristotle (*Metaph.*, iii. 2, and *Analyt. Post.*, i. 11), the art of conversation directed to the mutual investigation of truth, especially philosophical truth. But a conversation of this kind necessarily passes more or less into controversy; therefore dialectic may also be explained as the art of disputation. We have examples and patterns of dialectic in the Platonic dialogues; but for the special theory of it, thus for the technical rules of disputation, eristics, very little has hitherto been accomplished. I have worked out an attempt of the kind, and given an example of it, in the second volume of the "Parerga," therefore I shall pass over the exposition of this science altogether here.

In Rhetoric the rhetorical figures are very much what the syllogistic figures are in Logic; at all events they are worth considering. In Aristotle's time they seem to have not yet become the object of theoretical investigation, for he does not treat of them in any of his rhetorics, and in this reference we are referred to Rutilius Lupus, the epitomiser of a later Gorgias.

All the three sciences have this in common, that without having learned them we follow their rules, which indeed are themselves first abstracted from this natural employment of them. Therefore, although they are of great theoretical interest, they are of little practical use; partly because, though they certainly give the rule, they do not give the case of its application; partly because in practice there is generally no time to recollect the rules. Thus they teach only what every one already knows and practises of his own accord; but yet the abstract knowledge of this is interesting and important. Logic will not easily have a practical value, at least for our own thinking. For the errors of our own reasoning scarcely ever lie in the inferences nor otherwise in the form, but in the judgments, thus in the matter of thought. In controversy, on the other hand, we can sometimes

derive some practical use from logic, by taking the more or less intentionally deceptive argument of our opponent, which he advances under the garb and cover of continuous speech, and referring it to the strict form of regular syllogisms, and thus convicting it of logical errors; for example, simple conversion of universal affirmative judgments, syllogisms with four terms, inferences from the consequent to the reason, syllogisms in the second figure with merely affirmative premisses, and many such.

It seems to me that the doctrine of the laws of thought might be simplified if we were only to set up two, the law of excluded middle and that of sufficient reason. The former thus: "Every predicate can either be affirmed or denied of every subject." Here it is already contained in the "either, or" that both cannot occur at once, and consequently just what is expressed by the laws of identity and contradiction. Thus these would be added as corollaries of that principle which really says that every two concept-spheres must be thought either as united or as separated, but never as both at once; and therefore, even although words are brought together which express the latter, these words assert a process of thought which cannot be carried out. The consciousness of this infeasibility is the feeling of contradiction. The second law of thought, the principle of sufficient reason, would affirm that the above attributing or denying must be determined by something different from the judgment itself, which may be a (pure or empirical) perception, or merely another judgment. This other and different thing is then called the ground or reason of the judgment. So far as a judgment satisfies the first law of thought, it is thinkable; so far as it satisfies the second, it is true, or at least in the case in which the ground of a judgment is only another judgment it is logically or formally true. But, finally, material or absolute truth is always the relation between a judgment and a perception, thus between the abstract and the concrete or perceptible idea. This is either an immediate relation or it is brought about by means of other judgments, *i.e.*, through other abstract ideas. From this it is easy to see that one truth can never overthrow another, but all must ultimately agree; because in the concrete or perceptible, which is their common foundation, no contradiction is possible. Therefore no truth has anything to fear from other truths. Illusion and error have to fear every truth, because through the logical connection of all truths even the most distant must some time strike its blow at every error. This second law of thought is therefore the connecting link between logic and what is no longer logic, but the matter of

thought. Consequently the agreement of the conceptions, thus of the abstract idea with what is given in the perceptible idea, is, on the side of the object *truth*, and on the side of the subject *knowledge*.

To express the union or separation of two concept-spheres referred to above is the work of the copula, "is — is not." Through this every verb can be expressed by means of its participle. Therefore all judging consists in the use of a verb, and *vice versâ*. Accordingly the significance of the copula is that the predicate is to be thought in the subject, nothing more. Now, consider what the content of the infinitive of the copula "to be" amounts to. But this is a principal theme of the professors of philosophy of the present time. However, we must not be too strict with them; most of them wish to express by it nothing but material things, the corporeal world, to which, as perfectly innocent realists at the bottom of their hearts, they attribute the highest reality. To speak, however, of the bodies so directly appears to them too vulgar; and therefore they say "being," which they think sounds better, and think in connection with it the tables and chairs standing before them.

"For, because, why, therefore, thus, since, although, indeed, yet, but, if, then, either, or," and more like these, are properly *logical particles*, for their only end is to express the form of the thought processes. They are therefore a valuable possession of a language, and do not belong to all in equal numbers. Thus "*zwar*" (the contracted "*es ist wahr*") seems to belong exclusively to the German language. It is always connected with an "*aber*" which follows or is added in thought, as "if" is connected with "then."

The logical rule that, as regards quantity, singular judgments, that is, judgments which have a singular conception (*notio singularis*) for their subject, are to be treated as *universal judgments*, depends upon the circumstance that they are in fact universal judgments, which have merely the peculiarity that their subject is a conception which can only be supported by a single real object, and therefore only contains a single real object under it; as when the conception is denoted by a proper name. This, however, has really only to be considered when we proceed from the abstract idea to the concrete or perceptible, thus seek to realise the conceptions. In thinking itself, in operating with judgments, this makes no difference, simply because between singular and universal conceptions there is no logical difference. "Immanuel Kant" signifies logically, "*all* Immanuel Kant." Accordingly the quantity of judgments is really only of two kinds — universal and particular. An *individual idea* cannot be the

subject of a judgment, because it is not an abstraction, it is not something thought, but something perceived. Every conception, on the other hand, is essentially universal, and every judgment must have a *conception* as its subject.

The difference between *particular judgments* (*propositiones particulares*) and *universal judgments* often depends merely on the external and contingent circumstance that the language has no word to express by itself the part that is here to be separated from the general conception which forms the subject of such a judgment. If there were such a word many a particular judgment would be universal. For example, the particular judgment, "Some trees bear gall-nuts," becomes a universal judgment, because for this part of the conception, "tree," we have a special word, "All oaks bear gall-nuts." In the same way is the judgment, "Some men are black," related to the judgment, "All negroes are black." Or else this difference depends upon the fact that in the mind of him who judges the conception which he makes the subject of the particular judgment has not become clearly separated from the general conception as a part of which he defines it; otherwise he could have expressed a universal instead of a particular judgment. For example, instead of the judgment, "Some ruminants have upper incisors," this, "All unhorned ruminants have upper incisors."

The *hypothetical and disjunctive judgments* are assertions as to the relation of two (in the case of the disjunctive judgment even several) categorical judgments to each other. The *hypothetical judgment* asserts that the truth of the second of the two categorical judgments here linked together depends upon the truth of the first, and the falseness of the first depends upon the falseness of the second; thus that these two propositions stand in direct community as regards truth and falseness. The *disjunctive judgment*, on the other hand, asserts that upon the truth of one of the categorical judgments here linked together depends the falseness of the others, and conversely; thus that these propositions are in conflict as regards truth and falseness. The *question* is a judgment, one of whose three parts is left open: thus either the copula, "Is Caius a Roman — or not?" or the predicate, "Is Caius a Roman — or something else?" or the subject, "Is Caius a Roman — or is it some one else who is a Roman?" The place of the conception which is left open may also remain quite empty; for example, "What is Caius?"— "Who is a Roman?"

The επαγωγη, inductio, is with Aristotle the opposite of the απαγωγη. The latter proves a proposition to be false by showing that what would follow from it is not true; thus by the *instantia in contrarium*. The επαγωγη, on the other hand, proves the truth of a proposition by showing that what would follow from it is true. Thus it leads by means of examples to our accepting something while the απαγωγη leads to our rejecting it. Therefore the επαγωγη, or induction, is an inference from the consequents to the reason, and indeed *modo ponente*; for from many cases it establishes the rule, from which these cases then in their turn follow. On this account it is never perfectly certain, but at the most arrives at very great probability. However, this *formal* uncertainty may yet leave room for *material* certainty through the number of the sequences observed; in the same way as in mathematics the irrational relations are brought infinitely near to rationality by means of decimal fractions. The απαγωγη, on the contrary, is primarily an inference from the reason to the consequents, though it is afterwards carried out *modo tollente*, in that it proves the non-existence of a necessary consequent, and thereby destroys the truth of the assumed reason. On this account it is always perfectly certain, and accomplishes more by a single example *in contrarium* than the induction does by innumerable examples in favour of the proposition propounded. So much easier is it to refute than to prove, to overthrow than to establish.

Chapter X. On The Syllogism.

Although it is very hard to establish a new and correct view of a subject which for more than two thousand years has been handled by innumerable writers, and which, moreover, does not receive additions through the growth of experience, yet this must not deter me from presenting to the thinker for examination the following attempt of this kind.

An inference is that operation of our reason by virtue of which, through the comparison of two judgments a third judgment arises, without the assistance of any knowledge otherwise obtained. The condition of this is that these two judgments have *one* conception in common, for otherwise they are foreign to each other and have no community. But under this condition they become the father and mother of a child that contains in itself something of both. Moreover, this operation is no arbitrary act, but an act of the reason, which, when it has considered such judgments, performs it of itself according to its own laws. So far it is objective, not subjective, and therefore subject to the strictest rules.

We may ask in passing whether he who draws an inference really learns something new from the new proposition, something previously unknown to him? Not absolutely; but yet to a certain extent he does. What he learns lay in what he knew: thus he knew it also, but he did not know that he knew it; which is as if he had something, but did not know that he had it, and this is just the same as if he had it not. He knew it only *implicite*, now he knows it *explicite*; but this distinction may be so great that the conclusion appears to him a new truth. For example:

All diamonds are stones;
All diamonds are combustible:
Therefore some stones are combustible.

The nature of inference consequently consists in this, that we bring it to distinct consciousness that we have already thought in the premisses what is asserted in the conclusion. It is therefore a means of becoming more distinctly conscious of one’s own knowledge, of learning more fully, or becoming aware of what one knows. The knowledge which is afforded by the conclusion was *latent*, and therefore had just as little effect as latent heat has on the thermometer. Whoever has salt has also chlorine; but it is as if he had it not, for it can only act as chlorine if it is chemically evolved; thus

only, then, does he really possess it. It is the same with the gain which a mere conclusion from already known premisses affords: a previously *bound or latent knowledge* is thereby set *free*. These comparisons may indeed seem to be somewhat strained, but yet they really are not. For because we draw many of the possible inferences from our knowledge very soon, very rapidly, and without formality, and therefore have no distinct recollection of them, it seems to us as if no premisses for possible conclusions remained long stored up unused, but as if we already had also conclusions prepared for all the premisses within reach of our knowledge. But this is not always the case; on the contrary, two premisses may have for a long time an isolated existence in the same mind, till at last some occasion brings them together, and then the conclusion suddenly appears, as the spark comes from the steel and the stone only when they are struck together. In reality the premisses assumed from without, both for theoretical insight and for motives, which bring about resolves, often lie for a long time in us, and become, partly through half-conscious, and even inarticulate, processes of thought, compared with the rest of our stock of knowledge, reflected upon, and, as it were, shaken up together, till at last the right major finds the right minor, and these immediately take up their proper places, and at once the conclusion exists as a light that has suddenly arisen for us, without any action on our part, as if it were an inspiration; for we cannot comprehend how we and others have so long been in ignorance of it. It is true that in a happily organised mind this process goes on more quickly and easily than in ordinary minds; and just because it is carried on spontaneously and without distinct consciousness it cannot be learned. Therefore Goethe says: "How easy anything is he knows who has discovered it, he knows who has attained to it." As an illustration of the process of thought here described we may compare it to those padlocks which consist of rings with letters; hanging on the box of a travelling carriage, they are shaken so long that at last the letters of the word come together in their order and the lock opens. For the rest, we must also remember that the syllogism consists in the process of thought itself, and the words and propositions through which it is expressed only indicate the traces it has left behind it — they are related to it as the sound-figures of sand are related to the notes whose vibrations they express. When we reflect upon something, we collect our data, reduce them to judgments, which are all quickly brought together and compared, and thereby the conclusions which it is possible to draw from them are instantly

arrived at by means of the use of all the three syllogistic figures. Yet on account of the great rapidity of this operation only a few words are used, and sometimes none at all, and only the conclusion is formally expressed. Thus it sometimes happens that because in this way, or even merely intuitively, *i.e.*, by a happy *apperçu*, we have brought some new truth to consciousness, we now treat it as a conclusion and seek premisses for it, that is, we desire to prove it, for as a rule knowledge exists earlier than its proofs. We then go through our stock of knowledge in order to see whether we can find some truth in it in which the newly discovered truth was already implicitly contained, or two propositions which would give this as a result if they were brought together according to rule. On the other hand, every judicial proceeding affords a most complete and imposing syllogism, a syllogism in the first figure. The civil or criminal transgression complained of is the minor; it is established by the prosecutor. The law applicable to the case is the major. The judgment is the conclusion, which therefore, as something necessary, is "merely recognised" by the judge.

But now I shall attempt to give the simplest and most correct exposition of the peculiar mechanism of inference.

Judging, this elementary and most important process of thought, consists in the comparison of two *conceptions*; *inference* in the comparison of two *judgments*. Yet ordinarily in text-books inference is also referred to the comparison of conceptions, though of *three*, because from the relation which two of these conceptions have to a third their relation to each other may be known. Truth cannot be denied to this view also; and since it affords opportunity for the perceptible demonstration of syllogistic relations by means of drawn concept-spheres, a method approved of by me in the text, it has the advantage of making the matter easily comprehensible. But it seems to me that here, as in so many cases, comprehensibility is attained at the cost of thoroughness. The real process of thought in inference, with which the three syllogistic figures and their necessity precisely agree, is not thus recognised. In inference we operate *not* with mere *conceptions* but with whole *judgments*, to which quality, which lies only in the copula and not in the conceptions, and also quantity are absolutely essential, and indeed we have further to add modality. That exposition of inference as a relation of *three conceptions* fails in this, that it at once resolves the judgments into their ultimate elements (the conceptions), and thus the means of combining these is lost, and that which is peculiar to the judgments as such and in their

completeness, which is just what constitutes the necessity of the conclusion which follows from them, is lost sight of. It thus falls into an error analogous to that which organic chemistry would commit if, for example, in the analysis of plants it were at once to reduce them to their *ultimate* elements, when it would find in all plants carbon, hydrogen, and oxygen, but would lose the specific differences, to obtain which it is necessary to stop at their more special elements, the so-called alkaloids, and to take care to analyse these in their turn. From three given conceptions no conclusion can as yet be drawn. It may certainly be said: the relation of two of them to the third must be given with them. But it is just the *judgments* which combine these conceptions, that are the expression of this relation; thus *judgments*, not mere *conceptions*, are the material of the inference. Accordingly inference is essentially a comparison of two *judgments*. The process of thought in our mind is concerned with these and the thoughts expressed by them, not merely with three conceptions. This is the case even when this process is imperfectly or not at all expressed in words; and it is as such, as a bringing together of the complete and unanalysed judgments, that we must consider it in order properly to understand the technical procedure of inference. From this there will then also follow the necessity for three really rational syllogistic figures.

As in the exposition of syllogistic reasoning by means of *concept-spheres* these are presented to the mind under the form of circles, so in the exposition by means of entire judgments we have to think these under the form of rods, which, for the purpose of comparison, are held together now by one end, now by the other. The different ways in which this can take place give the three figures. Since now every premiss contains its subject and its predicate, these two conceptions are to be imagined as situated at the two ends of each rod. The two judgments are now compared with reference to the two *different* conceptions in them; for, as has already been said, the third conception must be the same in both, and is therefore subject to no comparison, but is that *with which*, that is, in reference to which, the other two are compared; it is the *middle*. The latter is accordingly always only the means and not the chief concern. The two different conceptions, on the other hand, are the subject of reflection, and to find out their relation to each other by means of the judgments in which they are contained is the aim of the syllogism. Therefore the conclusion speaks only of them, not of the middle, which was only a means, a measuring rod, which we let fall as soon

as it has served its end. Now if this conception which is *identical* in both propositions, thus the middle, is the subject of *one* premiss, the conception to be compared with it must be the predicate, and conversely. Here at once is established *a priori* the possibility of three cases; either the subject of one premiss is compared with the predicate of the other, or the subject of the one with the subject of the other, or, finally, the predicate of the one with the predicate of the other. Hence arise the three syllogistic figures of Aristotle; the fourth, which was added somewhat impertinently, is ungenuine and a spurious form. It is attributed to Galenus, but this rests only on Arabian authority. Each of the three figures exhibits a perfectly different, correct, and natural thought-process of the reason in inference.

If in the two judgments to be compared the relation between the *predicate of the one and the subject of the other* is the object of the comparison, the *first figure* appears. This figure alone has the advantage that the conceptions which in the conclusion are subject and predicate both appear already in the same character in the premisses; while in the two other figures one of them must always change its roll in the conclusion. But thus in the first figure the result is always less novel and surprising than in the other two. Now this advantage in the first figure is obtained by the fact that the predicate of the major is compared with the subject of the minor, but not conversely, which is therefore here essential, and involves that the middle should assume both the positions, *i.e.*, it is the subject in the major and the predicate in the minor. And from this again arises its subordinate significance, for it appears as a mere weight which we lay at pleasure now in one scale and now in the other. The course of thought in this figure is, that the predicate of the major is attributed to the subject of the minor, because the subject of the major is the predicate of the minor, or, in the negative case, the converse holds for the same reason. Thus here a property is attributed to the things thought through a conception, because it depends upon another property which we already know they possess; or conversely. Therefore here the guiding principle is: *Nota notæ est nota rei ipsius, et repugnans notæ repugnat rei ipsi*.

If, on the other hand, we compare two judgments with the intention of bringing out the relation which the *subjects of both* may have to each other, we must take as the common measure their predicate. This will accordingly be here the middle, and must therefore be the same in both judgments. Hence arises the *second figure*. In it the relation of two subjects to each

other is determined by that which they have as their common predicate. But this relation can only have significance if the same predicate is attributed to the one subject and denied of the other, for thus it becomes an essential ground of distinction between the two. For if it were attributed to both the subjects this could decide nothing as to their relation to each other, for almost every predicate belongs to innumerable subjects. Still less would it decide this relation if the predicate were denied of both the subjects. From this follows the fundamental characteristic of the second figure, that the premisses must be of *opposite quality*; the one must affirm and the other deny. Therefore here the principal rule is: *Sit altera negans*; the corollary of which is: *E meris affirmativis nihil sequitur*; a rule which is sometimes transgressed in a loose argument obscured by many parenthetical propositions. The course of thought which this figure exhibits distinctly appears from what has been said. It is the investigation of two kinds of things with the view of distinguishing them, thus of establishing that they are *not* of the same species; which is here decided by showing that a certain property is essential to the one kind, which the other lacks. That this course of thought assumes the second figure of its own accord, and expresses itself clearly only in it, will be shown by an example:

All fishes have cold blood;

No whale has cold blood:

Thus no whale is a fish.

In the first figure, on the other hand, this thought exhibits itself in a weak, forced, and ultimately patched-up form:

Nothing that has cold blood is a whale;

All fishes have cold blood:

Thus no fish is a whale,

And consequently no whale is a fish.

Take also an example with an affirmative minor:

No Mohamedan is a Jew;

Some Turks are Jews:

Therefore some Turks are not Mohamedans.

As the guiding principle for this figure I therefore give, for the mood with the negative minor: *Cui repugnat nota, etiam repugnat notatum*; and for the mood with the affirmative minor: *Notato repugnat id cui nota repugnat*. Translated these may be thus combined: Two subjects which

stand in opposite relations to one predicate have a negative relation to each other.

The third case is that in which we place two judgments together in order to investigate the relation of their *predicates*. Hence arises the *third figure*, in which accordingly the middle appears in both premisses as the subject. It is also here the *tertium comparationis*, the measure which is applied to both the conceptions which are to be investigated, or, as it were, a chemical reagent, with which we test them both in order to learn from their relation to it what relation exists between themselves. Thus, then, the conclusion declares whether a relation of subject and predicate exists between the two, and to what extent this is the case. Accordingly, what exhibits itself in this figure is reflection concerning two properties which we are inclined to regard either as *incompatible*, or else as *inseparable*, and in order to decide this we attempt to make them the predicates of one subject in two judgments. From this it results either that both properties belong to the same thing, consequently their *compatibility*, or else that a thing has the one but not the other, consequently their *separableness*. The former in all moods with two affirmative premisses, the latter in all moods with one negative; for example:

Some brutes can speak;

All brutes are irrational:

Therefore some irrational beings can speak.

According to Kant (*Die Falsche Spitzfinigkeit*, § 4) this inference would only be conclusive if we added in thought: “Therefore some irrational beings are brutes.” But this seems to be here quite superfluous and by no means the natural process of thought. But in order to carry out the same process of thought directly by means of the first figure I must say:

“All brutes are irrational;

Some beings that can speak are brutes,”

which is clearly not the natural course of thought; indeed the conclusion which would then follow, “Some beings that can speak are irrational,” would have to be converted in order to preserve the conclusion which the third figure gives of itself, and at which the whole course of thought has aimed. Let us take another example:

All alkalis float in water;

All alkalis are metals:

Therefore some metals float in water.

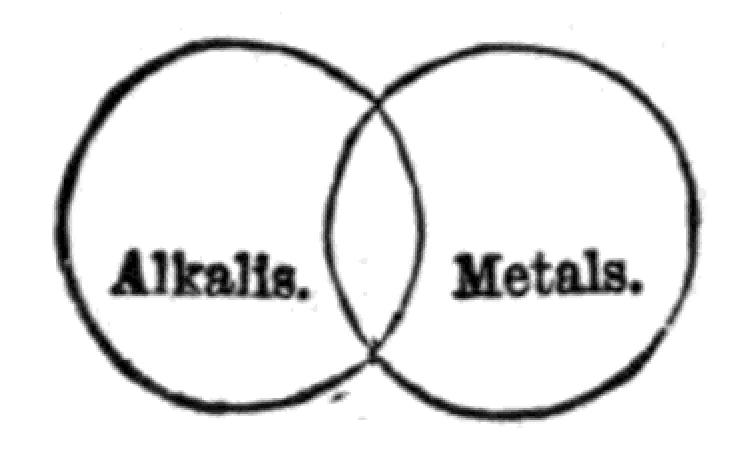

Figure 1

Figure 2

When this is transposed into the first figure the minor must be converted, and thus runs: "Some metals are alkalis." It therefore merely asserts that some metals lie in the sphere "alkalis," thus [Figure 1], while our actual knowledge is that all alkalis lie in the sphere "metals," thus [Figure 2]: It follows that if the first figure is to be regarded as the only normal one, in order to think naturally we would have to think less than we know, and to think indefinitely while we know definitely. This assumption has too much against it. Thus in general it must be denied that when we draw inferences in the second and third figures we tacitly convert a proposition. On the contrary, the third, and also the second, figure exhibits just as rational a process of thought as the first. Let us now consider another example of the other class of the third figure, in which the separableness of two predicates is the result; on account of which one premiss must here be negative:

No Buddhist believes in a God;

Some Buddhists are rational:

Therefore some rational beings do not believe in a God.

As in the examples given above the *compatibility* of two properties is the problem of reflection, now their *separableness* is its problem, which here also must be decided by comparing them with *one* subject and showing that *one* of them is present in it without the *other*. Thus the end is directly attained, while by means of the first figure it could only be attained indirectly. For in order to reduce the syllogism to the first figure we must convert the minor, and therefore say: "Some rational beings are Buddhists," which would be only a faulty expression of its meaning, which really is: "Some Buddhists are yet certainly rational."

As the guiding principle of this figure I therefore give: for the affirmative moods: *Ejusdem rei notœ, modo sit altera universalis, sibi invicem sunt notœ particulares*; and for the negative moods: *Nota rei competens, notœ eidem repugnanti, particulariter repugnat, modo sit altera universalis*. Translated: If two predicates are affirmed of one subject, and at least one of them universally, they are also affirmed of each other particularly; and, on the contrary, they are denied of each other particularly whenever one of them contradicts the subject of which the other is affirmed; provided always that either the contradiction or the affirmation be universal.

In the *fourth figure* the subject of the major has to be compared with the predicate of the minor; but in the conclusion they must both exchange their value and position, so that what was the subject of the major appears as the

predicate of the conclusion, and what was the predicate of the minor appears as the subject of the conclusion. By this it becomes apparent that this figure is merely the *first*, wilfully turned upside down, and by no means the expression of a real process of thought natural to the reason.

On the other hand, the first three figures are the ectypes of three real and essentially different operations of thought. They have this in common, that they consist in the comparison of two judgments; but such a comparison only becomes fruitful when these judgments have *one* conception in common. If we present the premisses to our imagination under the sensible form of two rods, we can think of this conception as a clasp that links them to each other; indeed in lecturing one might provide oneself with such rods. On the other hand, the three figures are distinguished by this, that those judgments are compared either with reference to the subjects of both, or to the predicates of both, or lastly, with reference to the subject of the one and the predicate of the other. Since now every conception has the property of being subject or predicate only because it is already part of a judgment, this confirms my view that in the syllogism only judgments are primarily compared, and conceptions only because they are parts of judgments. In the comparison of two judgments, however, the essential question is, in *respect of what* are they compared? not *by what means* are they compared? The former consists of the concepts which are different in the two judgments; the latter consists of the middle, that is, the conception which is identical in both. It is therefore not the right point of view which Lambert, and indeed really Aristotle, and almost all the moderns have taken in starting from the *middle* in the analysis of syllogisms, and making it the principal matter and its position the essential characteristic of the syllogisms. On the contrary, its role is only secondary, and its position a consequence of the logical value of the conceptions which are really to be compared in the syllogism. These may be compared to two substances which are to be chemically tested, and the middle to the reagent by which they are tested. It therefore always takes the place which the conceptions to be compared leave vacant, and does not appear again in the conclusion. It is selected according to our knowledge of its relation to both the conceptions and its suitableness for the place it has to take up. Therefore in many cases we can change it at pleasure for another without affecting the syllogism. For example, in the syllogism:

All men are mortal;

Caius is a man:

I can exchange the middle “man” for “animal existence.” In the syllogism:

All diamonds are stones;

All diamonds are combustible:

I can exchange the middle “diamond” for “anthracite.” As an external mark by which we can recognise at once the figure of a syllogism the middle is certainly very useful. But as the fundamental characteristic of a thing which is to be explained, we must take what is essential to it; and what is essential here is, whether we place two propositions together in order to compare their predicates or their subjects, or the predicate of the one and the subject of the other.

Therefore, in order as premisses to yield a conclusion, two judgments must have a conception in common; further, they must not both be negative, nor both particular; and lastly, in the case in which the conceptions to be compared are the subjects of both, they must not both be affirmative.

The voltaic pile may be regarded as a sensible image of the syllogism. Its point of indifference, at the centre, represents the middle, which holds together the two premisses, and by virtue of which they have the power of yielding a conclusion. The two different conceptions, on the other hand, which are really what is to be compared, are represented by the two opposite poles of the pile. Only because these are brought together by means of their two conducting wires, which represent the copulas of the two judgments, is the spark emitted upon their contact — the new light of the conclusion.

Chapter XI.[22] On Rhetoric.

Eloquence is the faculty of awakening in others our view of a thing, or our opinion about it, of kindling in them our feeling concerning it, and thus putting them in sympathy with us. And all this by conducting the stream of our thought into their minds, through the medium of words, with such force as to carry their thought from the direction it has already taken, and sweep it along with ours in its course. The more their previous course of thought differs from ours, the greater is this achievement. From this it is easily understood how personal conviction and passion make a man eloquent; and in general, eloquence is more the gift of nature than the work of art; yet here, also, art will support nature.

In order to convince another of a truth which conflicts with an error he firmly holds, the first rule to be observed, is an easy and natural one: *let the premisses come first, and the conclusion follow*. Yet this rule is seldom observed, but reversed; for zeal, eagerness, and dogmatic positiveness urge us to proclaim the conclusion loudly and noisily against him who adheres to the opposed error. This easily makes him shy, and now he opposes his will to all reasons and premisses, knowing already to what conclusion they lead. Therefore we ought rather to keep the conclusion completely concealed, and only advance the premisses distinctly, fully, and in different lights. Indeed, if possible, we ought not to express the conclusion at all. It will come necessarily and regularly of its own accord into the reason of the hearers, and the conviction thus born in themselves will be all the more genuine, and will also be accompanied by self-esteem instead of shame. In difficult cases we may even assume the air of desiring to arrive at a quite opposite conclusion from that which we really have in view. An example of this is the famous speech of Antony in Shakspeare's "Julius Cæsar."

In defending a thing many persons err by confidently advancing everything imaginable that can be said for it, mixing up together what is true, half true, and merely plausible. But the false is soon recognised, or at any rate felt, and throws suspicion also upon the cogent and true arguments which were brought forward along with it. Give then the true and weighty pure and alone, and beware of defending a truth with inadequate, and therefore, since they are set up as adequate, sophistical reasons; for the opponent upsets these, and thereby gains the appearance of having upset the

truth itself which was supported by them, that is, he makes *argumenta ad hominem* hold good as *argumenta ad rem*. The Chinese go, perhaps, too far the other way, for they have the saying: “He who is eloquent and has a sharp tongue may always leave half of a sentence unspoken; and he who has right on his side may confidently yield three-tenths of his assertion.”

Chapter XII.[23] On The Doctrine Of Science.

From the analysis of the different functions of our intellect given in the whole of the preceding chapters, it is clear that for a correct use of it, either in a theoretical or a practical reference, the following conditions are demanded: (1.) The correct apprehension through perception of the real things taken into consideration, and of all their essential properties and relations, thus of all *data*. (2.) The construction of correct conceptions out of these; thus the connotation of those properties under correct abstractions, which now become the material of the subsequent thinking. (3.) The comparison of those conceptions both with the perceived object and among themselves, and with the rest of our store of conceptions, so that correct judgments, pertinent to the matter in hand, and fully comprehending and exhausting it, may proceed from them; thus the right *estimation* of the matter. (4.) The placing together or *combination* of those judgments as the premisses of *syllogisms*. This may be done very differently according to the choice and arrangement of the judgments, and yet the actual *result* of the whole operation primarily depends upon it. What is really of importance here is that from among so many possible combinations of those different judgments which have to do with the matter free deliberation should hit upon the very ones which serve the purpose and are decisive. But if in the first function, that is, in the apprehension through perception of the things and relations, any single essential point has been overlooked, the correctness of all the succeeding operations of the mind cannot prevent the result from being false; for there lie the data, the material of the whole investigation. Without the certainty that these are correctly and completely collected, one ought to abstain, in important matters, from any definite decision.

A conception is *correct*; a judgment is *true*; a body is *real*; and a relation is *evident*. A proposition of immediate certainty is an *axiom*. Only the fundamental principles of logic, and those of mathematics drawn *a priori* from intuition or perception, and finally also the law of causality, have immediate certainty. A proposition of indirect certainty is a maxim, and that by means of which it obtains its certainty is the proof. If immediate certainty is attributed to a proposition which has no such certainty, this is a *petitio principii*. A proposition which appeals directly to the empirical

perception is an *assertion*: to confront it with such perception demands judgment. Empirical perception can primarily afford us only *particular*, not universal truths. Through manifold repetition and confirmation such truths indeed obtain a certain universality also, but it is only comparative and precarious, because it is still always open to attack. But if a proposition has absolute universality, the perception to which it appeals is not empirical but *a priori*. Thus Logic and Mathematics alone are absolutely certain sciences; but they really teach us only what we already knew beforehand. For they are merely explanations of that of which we are conscious *a priori*, the forms of our own knowledge, the one being concerned with the forms of thinking, the other with those of perceiving. Therefore we spin them entirely out of ourselves. All other scientific knowledge is empirical.

A proof proves *too much* if it extends to things or cases of which that which is to be proved clearly does not hold good; therefore it is refuted apagogically by these. The *deductio ad absurdum* properly consists in this, that we take a false assertion which has been made as the major proposition of a syllogism, then add to it a correct minor, and arrive at a conclusion which clearly contradicts facts of experience or unquestionable truths. But by some round-about way such a refutation must be possible of every false doctrine. For the defender of this will yet certainly recognise and admit some truth or other, and then the consequences of this, and on the other hand those of the false assertion, must be followed out until we arrive at two propositions which directly contradict each other. We find many examples in Plato of this beautiful artifice of genuine dialectic.

A *correct hypothesis* is nothing more than the true and complete expression of the present fact, which the originator of the hypothesis has intuitively apprehended in its real nature and inner connection. For it tells us only what really takes place here.

The opposition of the *analytical* and *synthetical* methods we find already indicated by Aristotle, yet perhaps first distinctly described by Proclus, who says quite correctly: “Μεθοδοι δε παραδιδονται; καλλιστη μεν ἡ δια της αναλυσεως επ᾽ αρχην ὁμολογουμενην αναγουσα το ζητουμενον; ἡν και Πλατων, ὡς φασι, Λαοδαμαντι παρεδωκεν. κ.τ.λ.” (*Methodi traduntur sequentes: pulcherrima quidem ea, quæ per analysin quæsitum refert ad principium, de quo jam convenit; quam etiam Plato Laodamanti tradidisse dicitur.*) “*In Primum Euclidis Librum*,” L. iii. Certainly the analytical

method consists in referring what is given to an admitted principle; the synthetical method, on the contrary, in deduction from such a principle. They are therefore analogous to the επαγωγη and απαγωγη explained in chapter ix.; only the latter are not used to establish propositions, but always to overthrow them. The analytical method proceeds from the facts; the particular, to the principle or rule; the universal, or from the consequents to the reasons; the other conversely. Therefore it would be much more correct to call them *the inductive and the deductive methods*, for the customary names are unsuitable and do not fully express the things.

If a philosopher tries to begin by thinking out the methods in accordance with which he will philosophise, he is like a poet who first writes a system of æsthetics in order to poetise in accordance with it. Both of them may be compared to a man who first sings himself a tune and afterwards dances to it. The thinking mind must find its way from original tendency. Rule and application, method and achievement, must, like matter and form, be inseparable. But after we have reached the goal we may consider the path we have followed. Æsthetics and methodology are, from their nature, younger than poetry and philosophy; as grammar is younger than language, thorough bass younger than music, and logic younger than thought.

This is a fitting place to make, in passing, a remark by means of which I should like to check a growing evil while there is yet time. That Latin has ceased to be the language of all scientific investigations has the disadvantage that there is no longer an immediately common scientific literature for the whole of Europe, but national literatures. And thus every scholar is primarily limited to a much smaller public, and moreover to a public hampered with national points of view and prejudices. Then he must now learn the four principal European languages, as well as the two ancient languages. In this it will be a great assistance to him that the *termini technici* of all sciences (with the exception of mineralogy) are, as an inheritance from our predecessors, Latin or Greek. Therefore all nations wisely retain these. Only the Germans have hit upon the unfortunate idea of wishing to Germanise the *termini technici* of all the sciences. This has two great disadvantages. First, the foreign and also the German scholar is obliged to learn all the technical terms of his science twice, which, when there are many — for example, in Anatomy — is an incredibly tiresome and lengthy business. If the other nations were not in this respect wiser than the Germans, we would have the trouble of learning every *terminus*

technicus five times. If the Germans carry this further, foreign men of learning will leave their books altogether unread; for besides this fault they are for the most part too diffuse, and are written in a careless, bad, and often affected and objectionable style, and besides are generally conceived with a rude disregard of the reader and his requirements. Secondly, those Germanised forms of the *termini technici* are almost throughout long, patched-up, stupidly chosen, awkward, jarring words, not clearly separated from the rest of the language, which therefore impress themselves with difficulty upon the memory, while the Greek and Latin expressions chosen by the ancient and memorable founders of the sciences possess the whole of the opposite good qualities, and easily impress themselves on the memory by their sonorous sound. What an ugly, harsh-sounding word, for instance, is "*Stickstoff*" instead of *azot*! "*Verbum*," "*substantiv*," "*adjectiv*," are remembered and distinguished more easily than "*Zeitwort*," "*Nennwort*," "*Beiwort*," or even "*Umstandswort*" instead of "*adverbium*." In Anatomy it is quite unsupportable, and moreover vulgar and low. Even "*Pulsader*" and "*Blutader*" are more exposed to momentary confusion than "*Arterie*" and "*Vene*;" but utterly bewildering are such expressions as "*Fruchthälter*," "*Fruchtgang*," and "*Fruchtleiter*" instead of "*uterus*," "*vagina*," and "*tuba Faloppii*," which yet every doctor must know, and which he will find sufficient in all European languages. In the same way "*Speiche*" and "*Ellenbogenröhre*" instead of "*radius*" and "*ulna*," which all Europe has understood for thousands of years. Wherefore then this clumsy, confusing, drawling, and awkward Germanising? Not less objectionable is the translation of the technical terms in Logic, in which our gifted professors of philosophy are the creators of a new terminology, and almost every one of them has his own. With G. E. Schulze, for example, the subject is called "*Grundbegriff*," the predicate "*Beilegungsbegriff*;" then there are "*Beilegungsschlüsse*," "*Voraussetzungsschlüsse*," and "*Entgegensetzungsschlüsse*;" the judgments have "*Grösse*," "*Beschaffenheit*," "*Verhältniss*," and "*Zuverlässigkeit*," *i.e.*, quantity, quality, relation, and modality. The same perverse influence of this Germanising mania is to be found in all the sciences. The Latin and Greek expressions have the further advantage that they stamp the scientific conception as such, and distinguish it from the words of common intercourse, and the ideas which cling to them through association; while,

for example, “*Speisebrei*” instead of *chyme* seems to refer to the food of little children, and “*Lungensack*” instead of *pleura*, and “*Herzbeutel*” instead of *pericardium* seem to have been invented by butchers rather than anatomists. Besides this, the most immediate necessity of learning the ancient languages depends upon the old *termini technici*, and they are more and more in danger of being neglected through the use of living languages in learned investigations. But if it comes to this, if the spirit of the ancients bound up with their languages disappears from a liberal education, then coarseness, insipidity, and vulgarity will take possession of the whole of literature. For the works of the ancients are the pole-star of every artistic or literary effort; if it sets they are lost. Even now we can observe from the miserable and puerile style of most writers that they have never written Latin.[24] The study of the classical authors is very properly called the study of *Humanity*, for through it the student first becomes a *man* again, for he enters into the world which was still free from all the absurdities of the Middle Ages and of romanticism, which afterwards penetrated so deeply into mankind in Europe that even now every one comes into the world covered with it, and has first to strip it off simply to become a man again. Think not that your modern wisdom can ever supply the place of that initiation into manhood; ye are not, like the Greeks and Romans, born freemen, unfettered sons of nature. Ye are first the sons and heirs of the barbarous Middle Ages and of their madness, of infamous priestcraft, and of half-brutal, half-childish chivalry. Though both now gradually approach their end, yet ye cannot yet stand on your own feet. Without the school of the ancients your literature will degenerate into vulgar gossip and dull philistinism. Thus for all these reasons it is my well-intended counsel that an end be put at once to the Germanising mania condemned above.

I shall further take the opportunity of denouncing here the disorder which for some years has been introduced into German orthography in an unprecedented manner. Scribblers of every species have heard something of conciseness of expression, but do not know that this consists in the careful omission of everything superfluous (to which, it is true, the whole of their writings belong), but imagine they can arrive at it by clipping the words as swindlers clip coin; and every syllable which appears to them superfluous, because they do not feel its value, they cut off without more ado. For example, our ancestors, with true tact, said “*Beweis*” and “*Verweis*;” but, on the other hand, “*Nachweisung*.” The fine distinction analogous to that

between "*Versuch*" and "*Versuchung*," "*Betracht*" and "*Betrachtung*," is not perceptible to dull ears and thick skulls; therefore they have invented the word "*Nachweis*," which has come at once into general use, for this only requires that an idea should be thoroughly awkward and a blunder very gross. Accordingly a similar amputation has already been proposed in innumerable words; for example, instead of "*Untersuchung*" is written "*Untersuch*;" nay, even instead of "*allmälig*," "*mälig*;" instead of "*beinahe*," "*nahe*;" instead of "*beständig*," "*ständig*." If a Frenchman took upon himself to write "*près*" instead of "*presque*," or if an Englishman wrote "*most*" instead of "*almost*," they would be laughed at by every one as fools; but in Germany whoever does this sort of thing passes for a man of originality. Chemists already write "*löslich*" and "*unlöslich*" instead of "*unauflöslich*," and if the grammarians do not rap them over the knuckles they will rob the language of a valuable word. Knots, shoe-strings, and also conglomerates of which the cement is softened, and all analogous things are "*löslich*" (can be loosed); but what is "*auflöslich*" (soluble), on the other hand, is whatever vanishes in a liquid, like salt in water. "*Auflösen*" (to dissolve) is the *terminus ad hoc*, which says this and nothing else, marking out a definite conception; but our acute improvers of the language wish to empty it into the general rinsing-pan "*lösen*" (to loosen); they would therefore in consistency be obliged to make "*lösen*" also take the place everywhere of "*ablösen*" (to relieve, used of guards), "*auslösen*" (to release), "*einlösen*" (to redeem), &c., and in these, as in the former case, deprive the language of definiteness of expression. But to make the language poorer by a word means to make the thought of the nation poorer by a conception. Yet this is the tendency of the united efforts of almost all our writers of books for the last ten or twenty years. For what I have shown here by *one* example can be supported by a hundred others, and the meanest stinting of syllables prevails like a disease. The miserable wretches actually count the letters, and do not hesitate to mutilate a word, or to use one in a false sense, whenever by doing so they can gain two letters. He who is capable of no new thoughts will at least bring new words to market, and every ink-slinger regards it as his vocation to improve the language. Journalists practise this most shamelessly; and since their papers, on account of the trivial nature of their contents, have the largest public, indeed a public which for the most part reads nothing else, a great danger threatens

the language through them. I therefore seriously advise that they should be subjected to an orthographical censorship, or that they should be made to pay a fine for every unusual or mutilated word; for what could be more improper than that changes of language should proceed from the lowest branch of literature? Language, especially a relatively speaking original language like German, is the most valuable inheritance of a nation, and it is also an exceedingly complicated work of art, easily injured, and which cannot again be restored, therefore a *noli me tangere*. Other nations have felt this, and have shown great piety towards their languages, although far less complete than German. Therefore the language of Dante and Petrarch differs only in trifles from that of to-day; Montaigne is still quite readable, and so also is Shakspeare in his oldest editions. For a German indeed it is good to have somewhat long words in his mouth; for he thinks slowly, and they give him time to reflect. But this prevailing economy of language shows itself in yet more characteristic phenomena. For example, in opposition to all logic and grammar, they use the imperfect for the perfect and pluperfect; they often stick the auxiliary verb in their pocket; they use the ablative instead of the genitive; for the sake of omitting a couple of logical particles they make such intricate sentences that one has to read them four times over in order to get at the sense; for it is only the paper and not the reader's time that they care to spare. In proper names, after the manner of Hottentots, they do not indicate the case either by inflection or article: the reader may guess it. But they are specially fond of contracting the double vowel and dropping the lengthening *h*, those letters sacred to prosody; which is just the same thing as if we wanted to banish η and ω from Greek, and make ε and ο take their place. Whoever writes *Scham*, *Märchen*, *Mass*, *Spass*, ought also to write *Lon*, *Son*, *Stat*, *Sat*, *Jar*, *Al*, &c. But since writing is the copy of speech, posterity will imagine that one ought to speak as one writes; and then of the German language there will only remain a narrow, mouth-distorting, jarring noise of consonants, and all prosody will be lost. The spelling "*Literatur*" instead of the correct "*Litteratur*" is also very much liked, because it saves a letter. In defence of this the participle of the verb *linere* is given as the root of the word. But *linere* means to smear; therefore the favoured spelling might actually be correct for the greater part of German bookmaking; so that one could distinguish a very small "*Litteratur*" from a very extensive "*Literatur.*" In order to write concisely let a man improve his style and shun all useless

gossip and chatter, and then he will not need to cut out syllables and letters on account of the dearness of paper. But to write so many useless pages, useless sheets, useless books, and then to want to make up this waste of time and paper at the cost of the innocent syllables and letters — that is truly the superlative of what is called in English being penny wise and pound foolish. It is to be regretted that there is no German Academy to take charge of the language against literary *sans-culottism*, especially in an age when even those who are ignorant of the ancient language venture to employ the press. I have expressed my mind more fully on the whole subject of the inexcusable mischief being done at the present day to the German language in my "Parerga," vol. ii. chap. 23.

In my essay on the principle of sufficient reason, § 51, I already proposed a first *classification of the sciences* in accordance with the form of the principle of sufficient reason which reigns in them; and I also touched upon it again in §§ 7 and 15 of the first volume of this work. I will give here a small attempt at such a classification, which will yet no doubt be susceptible of much improvement and perfecting: —

I. Pure *a priori* Sciences.

1. The doctrine of the ground of being.

(*a.*) In space: Geometry.

(*b.*) In time: Arithmetic and Algebra.

2. The doctrine of the ground of knowing: Logic.

II. Empirical or *a posteriori* Sciences. All based upon the ground of becoming, *i.e.*, the law of causality, and upon the three modes of that law.

1. The doctrine of causes.

(*a.*) Universal: Mechanics, Hydrodynamics, Physics, Chemistry.

(*b.*) Particular: Astronomy, Mineralogy, Geology, Technology, Pharmacy.

2. The doctrine of stimuli.

(*a.*) Universal: Physiology of plants and animals, together with the ancillary science, Anatomy.

(*b.*) Particular: Botany, Zoology, Zootomy, Comparative Physiology, Pathology, Therapeutics.

3. The doctrine of motives.

(*a.*) Universal: Ethics, Psychology.

(*b.*) Particular: Jurisprudence, History.

Philosophy or Metaphysics, as the doctrine of consciousness and its contents in general, or of the whole of experience as such, does not appear

in the list, because it does not at once pursue the investigation which the principle of sufficient reason prescribes, but first has this principle itself as its object. It is to be regarded as the thorough bass of all sciences, but belongs to a higher class than they do, and is almost as much related to art as to science. As in music every particular period must correspond to the tonality to which thorough bass has advanced, so every author, in proportion to the line he follows, must bear the stamp of the philosophy which prevails in his time. But besides this, every science has also its special philosophy; and therefore we speak of the philosophy of botany, of zoology, of history, &c. By this we must reasonably understand nothing more than the chief results of each science itself, regarded and comprehended from the highest, that is the most general, point of view which is possible within that science. These general results connect themselves directly with general philosophy, for they supply it with important data, and relieve it from the labour of seeking these itself in the philosophically raw material of the special sciences. These special philosophies therefore stand as a mediating link between their special sciences and philosophy proper. For since the latter has to give the most general explanations concerning the whole of things, these must also be capable of being brought down and applied to the individual of every species of thing. The philosophy of each science, however, arises independently of philosophy in general, from the data of its own science itself. Therefore it does not need to wait till that philosophy at last be found; but if worked out in advance it will certainly agree with the true universal philosophy. This, on the other hand, must be capable of receiving confirmation and illustration from the philosophies of the particular sciences; for the most general truth must be capable of being proved through the more special truths. Goethe has afforded a beautiful example of the philosophy of zoology in his reflections on Dalton's and Pander's skeletons of rodents (*Hefte zur Morphologie*, 1824). And like merit in connection with the same science belongs to Kielmayer, Delamark, Geoffroy St. Hilaire, Cuvier, and many others, in that they have all brought out clearly the complete analogy, the inner relationship, the permanent type, and systematic connection of animal forms. Empirical sciences pursued purely for their own sake and without philosophical tendency are like a face without eyes. They are, however, a suitable occupation for men of good capacity who yet lack the highest faculties, which would even be a

hindrance to minute investigations of such a kind. Such men concentrate their whole power and their whole knowledge upon one limited field, in which, therefore, on condition of remaining in entire ignorance of everything else, they can attain to the most complete knowledge possible; while the philosopher must survey all fields of knowledge, and indeed to a certain extent be at home in them; and thus that complete knowledge which can only be attained by the study of detail is necessarily denied him. Therefore the former may be compared to those Geneva workmen of whom one makes only wheels, another only springs, and a third only chains. The philosopher, on the other hand, is like the watchmaker, who alone produces a whole out of all these which has motion and significance. They may also be compared to the musicians of an orchestra, each of whom is master of his own instrument; and the philosopher, on the other hand, to the conductor, who must know the nature and use of every instrument, yet without being able to play them all, or even one of them, with great perfection. Scotus Erigena includes all sciences under the name *Scientia*, in opposition to philosophy, which he calls *Sapientia*. The same distinction was already made by the Pythagoreans; as may be seen from Stobæus (*Floril.*, vol. i. p. 20), where it is very clearly and neatly explained. But a much happier and more piquant comparison of the relation of the two kinds of mental effort to each other has been so often repeated by the ancients that we no longer know to whom it belongs. Diogenes Laertius (ii. 79) attributes it to Aristippus, Stobæus (*Floril.*, tit. iv. 110) to Aristo of Chios; the Scholiast of Aristotle ascribes it to him (p. 8 of the Berlin edition), but Plutarch (*De Puer. Educ.*, c. 10) attributes it to Bio— "*Qui ajebat, sicut Penelopes proci, quum non possent cum Penelope concumbere, rem cum ejus ancillis habuissent; ita qui philosophiam nequeunt apprehendere eos in alliis nullius pretii disciplinis sese conterere.*" In our predominantly empirical and historical age it can do no harm to recall this.

Chapter XIII.[25] On The Methods Of Mathematics.

Euclid's method of demonstration has brought forth from its own womb its most striking parody and caricature in the famous controversy on the theory of parallels, and the attempts, which are repeated every year, to prove the eleventh axiom. This axiom asserts, and indeed supports its assertion by the indirect evidence of a third intersecting line, that two lines inclining towards each other (for that is just the meaning of "less than two right angles") if produced far enough must meet — a truth which is supposed to be too complicated to pass as self-evident, and therefore requires a demonstration. Such a demonstration, however, cannot be produced, just because there is nothing that is not immediate. This scruple of conscience reminds me of Schiller's question of law: —

"For years I have used my nose for smelling. Have I, then, actually a right to it that can be proved?" Indeed it seems to me that the logical method is hereby reduced to absurdity. Yet it is just through the controversies about this, together with the vain attempts to prove what is *directly* certain as merely *indirectly* certain, that the self-sufficingness and clearness of intuitive evidence appears in contrast with the uselessness and difficulty of logical proof — a contrast which is no less instructive than amusing. The direct certainty is not allowed to be valid here, because it is no mere logical certainty following from the conceptions, thus resting only upon the relation of the predicate to the subject, according to the principle of contradiction. That axiom, however, is a synthetical proposition *a priori*, and as such has the guarantee of pure, not empirical, perception, which is just as immediate and certain as the principle of contradiction itself, from which all demonstrations first derive their certainty. Ultimately this holds good of every geometrical theorem, and it is quite arbitrary where we draw the line between what is directly certain and what has first to be demonstrated. It surprises me that the eighth axiom is not rather attacked. "Figures which coincide with each other are equal to each other." For "coinciding with each other" is either a mere tautology or something purely empirical which does not belong to pure perception but to external sensuous experience. It presupposes that the figures may be moved; but only matter is movable in space. Therefore this appeal to coincidence leaves pure space —

the one element of geometry — in order to pass over to what is material and empirical.

The reputed motto of the Platonic lecture-room, “Αγεωμετρητος μηδεις εισιτω,” of which mathematicians are so proud, was no doubt inspired by the fact that Plato regarded the geometrical figures as intermediate existences between the eternal Ideas and particular things, as Aristotle frequently mentions in his “Metaphysics” (especially i. c. 6, p. 887, 998, *et Scholia*, p. 827, ed. Berol.) Moreover, the opposition between those self-existent eternal forms, or Ideas, and the transitory individual things, was most easily made comprehensible in geometrical figures, and thereby laid the foundation of the doctrine of Ideas, which is the central point of the philosophy of Plato, and indeed his only serious and decided theoretical dogma. In expounding it, therefore, he started from geometry. In the same sense we are told that he regarded geometry as a preliminary exercise through which the mind of the pupil accustomed itself to deal with incorporeal objects, having hitherto in practical life had only to do with corporeal things (*Schol. in Aristot.*, p. 12, 15). This, then, is the sense in which Plato recommended geometry to the philosopher; and therefore one is not justified in extending it further. I rather recommend, as an investigation of the influence of mathematics upon our mental powers, and their value for scientific culture in general, a very thorough and learned discussion, in the form of a review of a book by Whewell in the *Edinburgh Review* of January 1836. Its author, who afterwards published it with some other discussions, with his name, is Sir W. Hamilton, Professor of Logic and Metaphysics in Scotland. This work has also found a German translator, and has appeared by itself under the title, “*Ueber den Werth und Unwerth der Mathematik*” *aus dem Englishen*, 1836. The conclusion the author arrives at is that the value of mathematics is only indirect, and lies in the application to ends which are only attainable through them; but in themselves mathematics leave the mind where they find it, and are by no means conducive to its general culture and development, nay, even a decided hindrance. This conclusion is not only proved by thorough dianoiological investigation of the mathematical activity of the mind, but is also confirmed by a very learned accumulation of examples and authorities. The only direct use which is left to mathematics is that it can accustom restless and unsteady minds to fix their attention. Even Descartes, who was yet himself famous as a mathematician, held the same opinion with regard

to mathematics. In the “*Vie de Descartes par Baillet*,” 1693, it is said, Liv. ii. c. 6, p. 54: “*Sa propre expérience l’avait convaincu du peu d’utilité des mathématiques, surtout lorsqu’on ne les cultive que pour elles mêmes.... Il ne voyait rien de moins solide, que de s’occuper de nombres tout simples et de figures imaginaires*,” &c.

Chapter XIV. On The Association Of Ideas.

The presence of ideas and thoughts in our consciousness is as strictly subordinated to the principle of sufficient reason in its different forms as the movement of bodies to the law of causality. It is just as little possible that a thought can appear in the mind without an occasion as that a body can be set in motion without a cause. Now this occasion is either *external*, thus an impression of the senses, or *internal*, thus itself also a thought which introduces another thought by means of *association*. This again depends either upon a relation of reason and consequent between the two; or upon similarity, even mere analogy; or lastly upon the circumstance that they were both first apprehended at the same time, which again may have its ground in the proximity in space of their objects. The last two cases are denoted by the word *à propos*. The predominance of one of these three bonds of association of thoughts over the others is characteristic of the intellectual worth of the man. The first named will predominate in thoughtful and profound minds, the second in witty, ingenious, and poetical minds, and the third in minds of limited capacity. Not less characteristic is the degree of facility with which one thought recalls others that stand in any kind of relation to it: this constitutes the activeness of the mind. But the impossibility of the appearance of a thought without its sufficient occasion, even when there is the strongest desire to call it up, is proved by all the cases in which we weary ourselves in vain to *recollect* something, and go through the whole store of our thoughts in order to find any one that may be associated with the one we seek; if we find the former, the latter is also found. Whoever wishes to call up something in his memory first seeks for a thread with which it is connected by the association of thoughts. Upon this depends mnemonics: it aims at providing us with easily found occasioners or causes for all the conceptions, thoughts, or words which are to be preserved. But the worst of it is that these occasioners themselves have first to be recalled, and this again requires an occasioner. How much the occasion accomplishes in memory may be shown in this way. If we have read in a book of anecdotes say fifty anecdotes, and then have laid it aside, immediately afterwards we will sometimes be unable to recollect a single one of them. But if the occasion comes, or if a thought occurs to us which has any analogy with one of those anecdotes, it immediately comes back to

us; and so with the whole fifty as opportunity offers. The same thing holds good of all that we read. Our immediate remembrance of words, that is, our remembrance of them without the assistance of mnemonic contrivances, and with it our whole faculty of speech, ultimately depends upon the direct association of thoughts. For the learning of language consists in this, that once for all we so connect a conception with a word that this word will always occur to us along with this conception, and this conception will always occur to us along with this word. We have afterwards to repeat the same process in learning every new language; yet if we learn a language for passive and not for active use — that is, to read, but not to speak, as, for example, most of us learn Greek — then the connection is one-sided, for the conception occurs to us along with the word, but the word does not always occur to us along with the conception. The same procedure as in language becomes apparent in the particular case, in the learning of every new proper name. But sometimes we do not trust ourselves to connect directly the name of *this* person, or town, river, mountain, plant, animal, &c., with the thought of each so firmly that it will call each of them up of itself; and then we assist ourselves mnemonically, and connect the image of the person or thing with any perceptible quality the name of which occurs in that of the person or thing. Yet this is only a temporary prop to lean on; later we let it drop, for the association of thoughts becomes an immediate support.

The search of memory for a clue shows itself in a peculiar manner in the case of a dream which we have forgotten on awaking, for in this case we seek in vain for that which a few minutes before occupied our minds with the strength of the clearest present, but now has entirely disappeared. We grasp at any lingering impression by which may hang the clue that by virtue of association would call that dream back again into our consciousness. According to Kieser, "*Tellurismus*," Bd. ii. § 271, memory even of what passed in magnetic-somnambular sleep may possibly sometimes be aroused by a sensible sign found when awake. It depends upon the same impossibility of the appearance of a thought without its occasion that if we propose to do anything at a definite time, this can only take place if we either think of nothing else till then, or if at the determined time we are *reminded* of it by something, which may either be an external impression arranged beforehand or a thought which is itself again brought about in the regular way. Both, then, belong to the class of motives. Every morning when we awake our consciousness is a *tabula rasa*, which, however,

quickly fills itself again. First it is the surroundings of the previous evening which now reappear, and remind us of what we thought in these surroundings; to this the events of the previous day link themselves on; and so one thought rapidly recalls the others, till all that occupied us yesterday is there again. Upon the fact that this takes place properly depends the health of the mind, as opposed to madness, which, as is shown in the third book, consists in the existence of great blanks in the memory of past events. But how completely sleep breaks the thread of memory, so that each morning it has to be taken up again, we see in particular cases of the incompleteness of this operation. For example, sometimes we cannot recall in the morning a melody which the night before ran in our head till we were tired of it.

The cases in which a thought or a picture of the fancy suddenly came into our mind without any conscious occasion seem to afford an exception to what has been said. Yet this is for the most part an illusion, which rests on the fact that the occasion was so trifling and the thought itself so vivid and interesting, that the former is instantly driven out of consciousness. Yet sometimes the cause of such an instantaneous appearance of an idea may be an internal physical impression either of the parts of the brain on each other or of the organic nervous system upon the brain.

In general our internal process of thought is in reality not so simple as the theory of it; for here it is involved in many ways. To make the matter clear to our imagination, let us compare our consciousness to a sheet of water of some depth. Then the distinctly conscious thoughts are merely the surface; while, on the other hand, the indistinct thoughts, the feelings, the after sensation of perceptions and of experience generally, mingled with the special disposition of our own will, which is the kernel of our being, is the mass of the water. Now the mass of the whole consciousness is more or less, in proportion to the intellectual activity, in constant motion, and what rise to the surface, in consequence of this, are the clear pictures of the fancy or the distinct, conscious thoughts expressed in words and the resolves of the will. The whole process of our thought and purpose seldom lies on the surface, that is, consists in a combination of distinctly thought judgments; although we strive against this in order that we may be able to explain our thought to ourselves and others. But ordinarily it is in the obscure depths of the mind that the rumination of the materials received from without takes place, through which they are worked up into thoughts; and it goes on

almost as unconsciously as the conversion of nourishment into the humours and substance of the body. Hence it is that we can often give no account of the origin of our deepest thoughts. They are the birth of our mysterious inner life. Judgments, thoughts, purposes, rise from out that deep unexpectedly and to our own surprise. A letter brings us unlooked-for and important news, in consequence of which our thoughts and motives are disordered; we get rid of the matter for the present, and think no more about it; but next day, or on the third or fourth day after, the whole situation sometimes stands distinctly before us, with what we have to do in the circumstances. Consciousness is the mere surface of our mind, of which, as of the earth, we do not know the inside, but only the crust.

But in the last instance, or in the secret of our inner being, what sets in activity the association of thought itself, the laws of which were set forth above, is the *will*, which urges its servant the intellect, according to the measure of its powers, to link thought to thought, to recall the similar, the contemporaneous, to recognise reasons and consequents. For it is to the interest of the will that, in general, one should think, so that one may be well equipped for all cases that may arise. Therefore the form of the principle of sufficient reason which governs the association of thoughts and keeps it active is ultimately the law of motivation. For that which rules the sensorium, and determines it to follow the analogy or other association of thoughts in this or that direction, is the will of the thinking subject. Now just as here the laws of the connection of ideas subsist only upon the basis of the will, so also in the real world the causal connection of bodies really subsists only upon the basis of the will, which manifests itself in the phenomena of this world. On this account the explanation from causes is never absolute and exhaustive, but leads back to forces of nature as their condition, and the inner being of the latter is just the will as thing in itself. In saying this, however, I have certainly anticipated the following book.

But because now the *outward* (sensible) occasions of the presence of our ideas, just as well as the *inner* occasions (those of association), and both independently of each other, constantly affect the consciousness, there arise from this the frequent interruptions of our course of thought, which introduce a certain cutting up and confusion of our thinking. This belongs to its imperfections which cannot be explained away, and which we shall now consider in a separate chapter.

Chapter XV. On The Essential Imperfections Of The Intellect.

Our self-consciousness has not space but only time as its form, and therefore we do not think in three dimensions, as we perceive, but only in *one*, thus in a line, without breadth or depth. This is the source of the greatest of the essential imperfections of our intellect. We can know all things only in *succession*, and can become conscious of only one at a time, indeed even of this one only under the condition that for the time we forget everything else, thus are absolutely unconscious of everything else, so that for the time it ceases to exist as far as we are concerned. In respect of this quality our intellect may be compared to a telescope with a very narrow field of vision; just because our consciousness is not stationary but fleeting. The intellect apprehends only successively, and in order to grasp one thing must let another go, retaining nothing but traces of it, which are ever becoming weaker. The thought which is vividly present to me now must after a little while have escaped me altogether; and if a good night's sleep intervene, it may be that I shall never find it again, unless it is connected with my personal interests, that is, with my will, which always commands the field.

Upon this imperfection of the intellect depends the disconnected and often *fragmentary nature* of our course of thought, which I have already touched on at the close of last chapter; and from this again arises the unavoidable *distraction* of our thinking. Sometimes external impressions of sense throng in upon it, disturbing and interrupting it, forcing different kinds of things upon it every moment; sometimes *one* thought draws in *another* by the bond of association, and is now itself dislodged by it; sometimes, lastly, the intellect itself is not capable of fixing itself very long and continuously at a time upon *one* thought, but as the eye when it gazes long at one object is soon unable to see it any more distinctly, because the outlines run into each other and become confused, until finally all is obscure, so through long-continued reflection upon one subject our thinking also is gradually confused, becomes dull, and ends in complete stupor. Therefore after a certain time, which varies with the individual, we must for the present give up every meditation or deliberation which has had the fortune to remain undisturbed, but yet has not been brought to an end, even

if it concerns a matter which is most important and pertinent to us; and we must dismiss from our consciousness the subject which interests us so much, however heavily our anxiety about it may weigh upon us, in order to occupy ourselves now with insignificant and indifferent things. During this time that important subject no longer exists for us; it is like the heat in cold water, *latent*. If now we resume it again at another time, we approach it like a new thing, with which we become acquainted anew, although more quickly, and the agreeable or disagreeable impression of it is also produced anew upon our will. We ourselves, however, do not come back quite unchanged. For with the physical composition of the humours and tension of the nerves, which constantly changes with the hours, days, and years, our mood and point of view also changes. Moreover, the different kinds of ideas which have been there in the meantime have left an echo behind them, the tone of which influences the ideas which follow. Therefore the same thing appears to us at different times, in the morning, in the evening, at mid-day, or on another day, often very different; opposite views of it now press upon each other and increase our doubt. Hence we speak of sleeping upon a matter, and for important determinations we demand a long time for consideration. Now, although this quality of our intellect, as springing from its weakness, has its evident disadvantages, yet, on the other hand, it affords the advantage that after the distraction and the physical change we return to our subject as comparatively new beings, fresh and strange, and thus are able to see it repeatedly in very different lights. From all this it is plain that human consciousness and thought is in its nature necessarily fragmentary, on account of which the theoretical and practical results which are achieved by piecing together such fragments are for the most part defective. In this our thinking consciousness is like a magic lantern, in the focus of which only one picture can appear at a time, and each, even if it represents the noblest objects, must yet soon pass away in order to make room for others of a different, and even most vulgar, description. In practical matters the most important plans and resolutions are formed in general; but others are subordinated to these as means to an end, and others again are subordinated to these, and so on down to the particular case that has to be carried out *in concreto*. They do not, however, come to be carried out in the order of their dignity, but while we are occupied with plans which are great and general, we have to contend with the most trifling details and the cares of the moment. In this way our consciousness becomes still more desultory. In

general, theoretical occupations of the mind unfit us for practical affairs, and *vice versâ*.

In consequence of the inevitably distracted and fragmentary nature of all our thinking, which has been pointed out, and the mingling of ideas of different kinds thereby introduced, to which even the noblest human minds are subject, we really have only *half a consciousness* with which to grope about in the labyrinth of our life and the obscurity of our investigations; bright moments sometimes illuminate our path like lightning. But what is to be expected of heads of which even the wisest is every night the scene of the strangest and most senseless dreams, and which has to take up its meditations again on awakening from these? Clearly a consciousness which is subject to such great limitations is little suited for solving the riddle of the world; and such an endeavour would necessarily appear strange and pitiful to a being of a higher order whose intellect had not time as its form, and whose thinking had thus true completeness and unity. Indeed it is really wonderful that we are not completely confused by the very heterogeneous mixture of ideas and fragments of thought of every kind which are constantly crossing each other in our minds, but are yet always able to see our way again and make everything agree together. Clearly there must exist a simpler thread upon which everything ranges itself together: but what is this? Memory alone is not sufficient, for it has essential limitations of which I shall speak shortly, and besides this, it is exceedingly imperfect and untrustworthy. The *logical ego* or even the *transcendental synthetic unity of apperception* are expressions and explanations which will not easily serve to make the matter comprehensible; they will rather suggest to many:

"'Tis true your beard is curly, yet it will not draw you the bolt."

Kant's proposition, "The *I think* must accompany all our ideas," is insufficient; for the "I" is an unknown quantity, *i.e.*, it is itself a secret. That which gives unity and connection to consciousness in that it runs through all its ideas, and is thus its substratum, its permanent supporter, cannot itself be conditioned by consciousness, therefore cannot be an idea. Rather it must be the *prius* of consciousness, and the root of the tree of which that is the fruit. This, I say, is the *will*. It alone is unchangeable and absolutely identical, and has brought forth consciousness for its own ends. Therefore it is also the will which gives it unity and holds together all its ideas and thoughts, accompanying them like a continuous harmony. Without it the intellect would no longer have the unity of consciousness, as a mirror in

which now this and now that successively presents itself, or at the most only so much as a convex mirror whose rays unite in an imaginary point behind its surface. But the *will* alone is that which is permanent and unchangeable in consciousness. It is the will which holds together all thoughts and ideas as means to its ends, and tinges them with the colour of its own character, its mood, and its interests, commands the attention, and holds in its hand the train of motives whose influence ultimately sets memory and the association of ideas in activity; at bottom it is the will that is spoken of whenever "I" appears in a judgment. Thus it is the true and final point of unity of consciousness, and the bond of all its functions and acts; it does not itself, however, belong to the intellect, but is only its root, source, and controller.

From the *form of time and the single dimension* of the series of ideas, on account of which, in order to take up one, the intellect must let all the others fall, there follows not only its distraction, but also its *forgetfulness*. Most of what it lets fall it never takes up again; especially since the taking up again is bound to the principle of sufficient reason, and thus demands an occasion which the association of thoughts and motivation have first to supply; an occasion, however, which may be the more remote and smaller in proportion as our sensibility for it is heightened by our interest in the subject. But memory, as I have already shown in the essay on the principle of sufficient reason, is not a store-house, but merely a faculty acquired by practice of calling up ideas at pleasure, which must therefore constantly be kept in practice by use; for otherwise it will gradually be lost. Accordingly the knowledge even of the learned man exists only *virtualiter* as an acquired facility in calling up certain ideas; *actualiter*, on the other hand, it also is confined to one idea, and is only conscious of this one at a time. Hence arises a strange contrast between what he knows *potentiâ* and what he knows *actu*; that is, between his knowledge and what he thinks at any moment: the former is an immense and always somewhat chaotic mass, the latter is a single distinct thought. The relation resembles that between the innumerable stars of the heavens and the limited field of vision of the telescope; it appears in a striking manner when upon some occasion he wishes to call distinctly to his remembrance some particular circumstance in his knowledge, and time and trouble are required to produce it from that chaos. Rapidity in doing this is a special gift, but is very dependent upon day and hour; therefore memory sometimes refuses us its service, even in

things which at another time it has readily at hand. This consideration calls us in our studies to strive more to attain to correct insight than to increase our learning, and to lay it to heart that the *quality* of knowledge is more important than its *quantity*. The latter imparts to books only thickness, the former thoroughness and also style; for it is an *intensive* quantity, while the other is merely *extensive*. It consists in the distinctness and completeness of the conceptions, together with the purity and accuracy of the knowledge of perception which forms their foundation; therefore the whole of knowledge in all its parts is penetrated by it, and in proportion as it is so is valuable or trifling. With a small quantity, but of good quality, one achieves more than with a very large quantity of bad quality.

The most perfect and satisfactory knowledge is that of perception, but it is limited absolutely to the particular, the individual. The combination of the many and the different in *one* idea is only possible through the *conception*, that is, through the omission of the differences; therefore this is a very imperfect manner of presenting things to the mind. Certainly the particular also can be directly comprehended as a universal, if it is raised to the (Platonic) Idea; but in this process, which I have analysed in the third book, the intellect already passes beyond the limits of individuality, and therefore of time; moreover it is only an exception.

These inner and essential imperfections of the intellect are further increased by a disturbance which, to a certain extent, is external to it, but yet is unceasing — the influence exerted by the will upon all its operations whenever it is in any way concerned in their result. Every passion, indeed every inclination and aversion, tinges the objects of knowledge with its colour. Of most common occurrence is the falsifying of knowledge which is brought about by wishes and hopes, for they picture to us the scarcely possible as probable and well nigh certain, and make us almost incapable of comprehending what is opposed to it: fear acts in a similar way; and every preconceived opinion, every partiality, and, as has been said, every interest, every emotion and inclination of the will, acts in an analogous manner.

To all these imperfections of the intellect we have finally to add this, that it grows old with the brain, that is, like all physiological functions, it loses its energy in later years, whereby all its imperfections are then much increased.

The defective nature of the intellect here set forth will not, however, surprise us if we look back at its origin and destiny as established by me in

the second book. Nature has produced it for the service of an individual will. Therefore it is only designed to know things so far as they afford the motives of such a will, but not to fathom them or comprehend their true being. Human intellect is only a higher gradation of the intellect of the brutes; and as this is entirely confined to the present, our intellect also bears strong traces of this limitation, Therefore our memory and recollection is something very imperfect. How little of all that we have done, experienced, learnt, or read, can we recall! And even this little for the most part only laboriously and imperfectly. For the same reasons is it so very difficult for us to keep ourselves free from the impressions of the present. Unconsciousness is the original and natural condition of all things, and therefore also the basis from which, in particular species of beings, consciousness results as their highest efflorescence; wherefore even then unconsciousness always continues to predominate. Accordingly most existences are without consciousness; but yet they act according to the laws of their nature, *i.e.*, of their will. Plants have at most a very weak analogue of consciousness; the lowest species of animals only the dawn of it. But even after it has ascended through the whole series of animals to man and his reason, the unconsciousness of plants, from which it started, still remains the foundation, and may be traced in the necessity for sleep, and also in all those essential and great imperfections, here set forth, of every intellect produced through physiological functions; and of another intellect we have no conception.

The imperfections here proved to be *essential* to the intellect are constantly increased, however, in particular cases, by *non-essential* imperfections. The intellect is never in *every* respect what it possibly might be. The perfections possible to it are so opposed that they exclude each other. Therefore no man can be at once Plato and Aristotle, or Shakspeare and Newton, or Kant and Goethe. The imperfections of the intellect, on the contrary, consort very well together; therefore in reality it for the most part remains far below what it might be. Its functions depend upon so very many conditions, which we can only comprehend as anatomical and physiological, in the *phenomenon* in which alone they are given us, that a decidedly excelling intellect, even in *one* respect alone, is among the rarest of natural phenomena. Therefore the productions of such an intellect are preserved through thousands of years, indeed every relic of such a highly favoured individual becomes a most valuable treasure. From such an

intellect down to that which approaches imbecility the gradations are innumerable. And primarily, in conformity with these gradations, the *mental horizon* of each of us varies very much from the mere comprehension of the present, which even the brute has, to that which also embraces the next hour, the day, even the morrow, the week, the year, the life, the century, the thousand years, up to that of the consciousness which has almost always present, even though obscurely dawning, the horizon of the infinite, and whose thoughts therefore assume a character in keeping with this. Further, that difference among intelligences shows itself in the rapidity of their thinking, which is very important, and which may be as different and as finely graduated as that of the points in the radius of a revolving disc. The remoteness of the consequents and reasons to which any one's thought can extend seems to stand in a certain relation to the rapidity of his thinking, for the greatest exertion of thought-power in general can only last quite a short time, and yet only while it lasts can a thought be thought out in its complete unity. It therefore amounts to this, how far the intellect can pursue it in so short a time, thus what length of path it can travel in it. On the other hand, in the case of some, rapidity may be made up for by the greater duration of that time of perfectly concentrated thought. Probably the slow and lasting thought makes the mathematical mind, while rapidity of thought makes the genius. The latter is a flight, the former a sure advance upon firm ground, step by step. Yet even in the sciences, whenever it is no longer a question of mere quantities, but of understanding the nature of phenomena, this last kind of thinking is inadequate. This is shown, for example, by Newton's theory of colour, and later by Biot's nonsense about colour rings, which yet agrees with the whole atomistic method of treating light among the French, with its *molécules de lumière*, and in general with their fixed idea of reducing everything in nature to mere mechanical effects. Lastly, the great individual diversity of intelligence we are speaking about shows itself excellently in the *degrees of the clearness of understanding*, and accordingly in the distinctness of *the whole thinking*. To one man that is to understand which to another is only in some degree to observe; the one is already done and at the goal while the other is only at the beginning; to the one that is the solution which to the other is only the problem. This depends on the *quality of thought* and knowledge, which was already referred to above. As in rooms the degree of light varies, so does it in minds. We can detect this *quality of the whole thought* as soon as we have read only a few

pages of an author. For in doing so we have been obliged to understand both with his understanding and in his sense; and therefore before we know all that he has thought we see already how he thinks, what is the *formal* nature, the *texture* of his thinking, which remains the same in everything about which he thinks, and whose expression is the train of thought and the style. In this we feel at once the pace, the flexibleness and lightness, even indeed the soaring power of his mind; or, on the contrary, its dulness, formality, lameness and leaden quality. For, as language is the expression of the mind of a nation, style is the more immediate expression of the mind of an author than even his physiognomy. We throw a book aside when we observe that in it we enter an obscurer region than our own, unless we have to learn from it mere facts, not thoughts. Apart from mere facts, only that author will afford us profit whose understanding is keener and clearer than our own, who forwards our thinking instead of hindering it, like the dull mind that will force us to keep pace with the toad-like course of its thought; thus that author with whose mind it gives us sensible relief and assistance sometimes to think, by whom we feel ourselves borne where we could not have gone alone. Goethe once said to me that if he read a page of Kant he felt as if he entered a brightly lighted room. Inferior minds are so not merely because they are distorted, and therefore judge falsely, but primarily through the *indistinctness* of their whole thinking, which may be compared to seeing through a bad telescope, when all the outlines appear indistinct and as if obliterated, and the different objects run into each other. The weak understanding of such minds shrinks from the demand for distinctness of conceptions, and therefore they do not themselves make this claim upon it, but put up with haziness; and to satisfy themselves with this they gladly have recourse to *words*, especially such as denote indefinite, very abstract, unusual conceptions which are hard to explain; such, for example, as infinite and finite, sensible and supersensible, the Idea of being, Ideas of the reason, the absolute, the Idea of the good, the divine, moral freedom, power of spontaneous generation, the absolute Idea, subject-object, &c. The like of these they confidently fling about, imagine they really express thoughts, and expect every one to be content with them; for the highest summit of wisdom which they can see is to have at command such ready-made words for every possible question. This immense *satisfaction in words* is thoroughly characteristic of inferior minds. It depends simply upon their incapacity for distinct conceptions, whenever these must rise above the most trivial and

simple relations. Hence upon the weakness and indolence of their intellect, and indeed upon the secret consciousness of this, which in the case of scholars is bound up with the early learnt and hard necessity of passing themselves off as thinking beings, to meet which demand in all cases they keep such a suitable store of ready-made words. It must really be amusing to see a professor of philosophy of this kind in the chair, who *bonâ fide* delivers such a juggle of words destitute of thoughts, quite sincerely, under the delusion that they are really thoughts, and in front of him the students, who just as *bonâ fide*, *i.e.*, under the same delusion, listen attentively and take notes, while yet in reality neither the one nor the other goes beyond the words, but rather these words themselves, together with the audible scratching of pens, are the only realities in the whole matter. This peculiar *satisfaction in words* has more than anything else to do with the perpetuation of errors. For, relying on the words and phrases received from his predecessors, each one confidently passes over obscurities and problems, and thus these are propagated through centuries from book to book; and the thinking man, especially in youth, is in doubt whether it may be that he is incapable of understanding it, or that there is really nothing here to understand; and similarly, whether for others the problem which they all slink past with such comical seriousness by the same path is no problem at all, or whether it is only that they will not see it. Many truths remain undiscovered simply on this account, that no one has the courage to look the problem in the face and grapple with it. On the contrary, the distinctness of thought and clearness of conceptions peculiar to eminent minds produces the effect that even known truths when brought forward by them gain new light, or at least a new stimulus. If we hear them or read them, it is as if we exchanged a bad telescope for a good one. Let one only read, for example, in Euler's "Letters to the Princess," his exposition of the fundamental truths of mechanics and optics. Upon this rests the remark of Diderot in the *Neveu de Rameau*, that only the perfect masters are capable of teaching really well the elements of a science; just because it is only they who really understand the questions, and for them words never take the place of thoughts.

But we ought to know that inferior minds are the rule, good minds the exception, eminent minds very rare, and genius a portent. How otherwise could a human race consisting of about eight hundred million individuals have left so much after six thousand years to discover, to invent, to think

out, and to say? The intellect is calculated for the support of the individual alone, and as a rule it is only barely sufficient even for this. But nature has wisely been very sparing of conferring a larger measure; for the man of limited intelligence can survey the few and simple relations which lie within reach of his narrow sphere of action, and can control the levers of them with much greater ease than could the eminently intellectual man who commands an incomparably larger sphere and works with long levers. Thus the insect sees everything on its stem or leaf with the most minute exactness, and better than we, and yet is not aware of the man who stands within three steps of it. This is the reason of the slyness of half-witted persons, and the ground of the paradox: *Il y a un mystère dans l'esprit des gens qui n'en ont pas*. For practical life genius is about as useful as an astral telescope in a theatre. Thus, with regard to the intellect nature is highly *aristocratic*. The distinctions which it has established are greater than those which are made in any country by birth, rank, wealth, or caste. But in the aristocracy of intellect, as in other aristocracies, there are many thousands of plebeians for one nobleman, many millions for one prince, and the great multitude of men are mere populace, mob, rabble, *la canaille*. Now certainly there is a glaring contrast between the scale of rank of nature and that of convention, and their agreement is only to be hoped for in a golden age. Meanwhile those who stand very high in the one scale of rank and in the other have this in common, that for the most part they live in exalted isolation, to which Byron refers when he says: —

"To feel me in the solitude of kings
Without the power that makes them bear a crown."
— *Proph. of Dante*, c. i.

For intellect is a differentiating, and therefore a separating principle. Its different grades, far more than those of mere culture, give to each man different conceptions, in consequence of which each man lives to a certain extent in a different world, in which he can directly meet those only who are like himself, and can only attempt to speak to the rest and make himself understood by them from a distance. Great differences in the grade and in the cultivation of the understanding fix a wide gulf between man and man, which can only be crossed by benevolence; for it is, on the contrary, the unifying principle, which identifies every one else with its own self. Yet the connection remains a moral one; it cannot become intellectual. Indeed,

when the degree of culture is about the same, the conversation between a man of great intellect and an ordinary man is like the journey together of two men, one of whom rides on a spirited horse and the other goes on foot. It soon becomes very trying to both of them, and for any length of time impossible. For a short way the rider can indeed dismount, in order to walk with the other, though even then the impatience of his horse will give him much to do.

But the public could be benefited by nothing so much as by the recognition of that *intellectual aristocracy of nature*. By virtue of such recognition it would comprehend that when facts are concerned, thus when the matter has to be decided from experiments, travels, codes, histories, and chronicles, the normal mind is certainly sufficient; but, on the other hand, when mere thoughts are in question, especially those thoughts the material or data of which are within reach of every one, thus when it is really only a question of *thinking before* others, decided reflectiveness, native eminence, which only nature bestows, and that very seldom, is inevitably demanded, and no one deserves to be heard who does not at once give proofs of this. If the public could be brought to see this for itself, it would no longer waste the time which is sparingly measured out to it for its culture on the productions of ordinary minds, thus on the innumerable botches of poetry and philosophy which are produced every day. It would no longer seize always what is newest, in the childish delusion that books, like eggs, must be enjoyed while they are fresh, but would confine itself to the works of the few select and chosen minds of all ages and nations, would strive to learn to know and understand them, and might thus by degrees attain to true culture. And then, also, those thousands of uncalled-for productions which, like tares, hinder the growth of the good wheat would be discontinued.

Chapter XVI.[26] On The Practical Use Of Reason And On Stoicism.

In the seventh chapter I have shown that, in the theoretical sphere, procedure based upon *conceptions* suffices for mediocre achievements only, while great achievements, on the other hand, demand that we should draw from perception itself as the primary source of all knowledge. In the practical sphere, however, the converse is the case. Here determination by what is perceived is the way of the brutes, but is unworthy of man, who has *conceptions* to guide his conduct, and is thus emancipated from the power of what is actually perceptibly present, to which the brute is unconditionally given over. In proportion as a man makes good this prerogative his conduct may be called *rational*, and only in this sense can we speak of *practical reason*, not in the Kantian sense, the inadmissibility of which I have thoroughly exposed in my prize essay on the foundation of morals.

It is not easy, however, to let oneself be determined by *conceptions* alone; for the directly present external world, with its perceptible reality, intrudes itself forcibly even on the strongest mind. But it is just in conquering this impression, in destroying its illusion, that the human spirit shows its worth and greatness. Thus if incitements to lust and pleasure leave it unaffected, if the threats and fury of enraged enemies do not shake it, if the entreaties of erring friends do not make its purpose waver, and the delusive forms with which preconcerted plots surround it leave it unmoved, if the scorn of fools and of the vulgar herd does not disturb it nor trouble it as to its own worth, then it seems to stand under the influence of a spirit-world, visible to it alone (and this is the world of conceptions), before which that perceptibly present world which lies open to all dissolves like a phantom. But, on the other hand, what gives to the external world and visible reality their great power over the mind is their nearness and directness. As the magnetic needle, which is kept in its position by the combined action of widely distributed forces of nature embracing the whole earth, can yet be perturbed and set in violent oscillation by a small piece of iron, if only it comes quite close to it, so even a great mind can sometimes be disconcerted and perturbed by trifling events and insignificant men, if only they affect it very closely, and the deliberate purpose can be for the moment shaken by a trivial but immediately present counter motive. For the

influence of the motives is subject to a law which is directly opposed to the law according to which weights act on a balance, and in consequence of it a very small motive, which, however, lies very near to us, can outweigh one which in itself is much stronger, but which only affects us from a distance. But it is this quality of the mind, by reason of which it allows itself to be determined in accordance with this law, and does not withdraw itself from it by the strength of actual practical reason, which the ancients denoted by *animi impotentia*, which really signifies *ratio regendæ voluntatis impotens*. Every *emotion* (*animi perturbatio*) simply arises from the fact that an idea which affects our will comes so excessively near to us that it conceals everything else from us, and we can no longer see anything but it, so that for the moment we become incapable of taking account of things of another kind. It would be a valuable safeguard against this if we were to bring ourselves to regard the present, by the assistance of imagination, as if it were past, and should thus accustom our apperception to the epistolary style of the Romans. Yet conversely we are very well able to regard what is long past as so vividly present that old emotions which have long been asleep are thereby reawakened in their full strength. Thus also no one would be irritated or disconcerted by a misfortune, a disappointment, if reason always kept present to him what man really is: the most needy of creatures, daily and hourly abandoned to innumerable misfortunes, great and small, το δειλοτατον ζωον, who has therefore to live in constant care and fear. Herodotus already says, "Παν εστι ανθρωπος συμφορα" (*homo totus est calamitas*).

The application of reason to practice primarily accomplishes this. It reconstructs what is one-sided and defective in knowledge of mere perception, and makes use of the contrasts or oppositions which it presents, to correct each other, so that thus the objectively true result is arrived at. For example, if we look simply at the bad action of a man we will condemn him; on the other hand, if we consider merely the need that moved him to it, we will compassionate him: reason, by means of its conceptions, weighs the two, and leads to the conclusion that he must be restrained, restricted, and curbed by a proportionate punishment.

I am again reminded here of Seneca's saying: "*Si vis tibi omnia subjicere, te subjice rationi*." Since, however, as was shown in the fourth book, the nature of suffering is positive, and that of pleasure negative, he who takes abstract or rational knowledge as the rule of his conduct, and

therefore constantly reflects on its consequences and on the future, will very frequently have to practise *sustine et abstine*, for in order to obtain the life that is most free from pain he generally sacrifices its keenest joys and pleasures, mindful of Aristotle's "ὀ φρονιμος το αλυπον διωκει, ου το ἡδυ" (*quod dolore vacat, non quod suave est, persequitur vir prudens*). Therefore with him the future constantly borrows from the present, instead of the present borrowing from the future, as is the case with a frivolous fool, who thus becomes impoverished and finally bankrupt. In the case of the former reason must, for the most part, assume the *rôle* of a churlish mentor, and unceasingly call for renunciations, without being able to promise anything in return, except a fairly painless existence. This rests on the fact that reason, by means of its conceptions, surveys the *whole* of life, whose outcome, in the happiest conceivable case, can be no other than what we have said.

When this striving after a painless existence, so far as it might be attainable by the application of and strict adherence to rational reflection and acquired knowledge of the true nature of life, was carried out with the greatest consistency and to the utmost extreme, it produced cynicism, from which stoicism afterwards proceeded. I wish briefly here to bring this out more fully for the sake of establishing more firmly the concluding exposition of our first book.

All ancient moral systems, with the single exception of that of Plato, were guides to a happy life. Accordingly in them the end of virtue was entirely in this life, not beyond death. For to them it is only the right path to a truly happy life; and on this account the wise choose it. Hence arise those lengthy debates chiefly preserved for us by Cicero, those keen and constantly renewed investigations, whether virtue quite alone and in itself is really sufficient for a happy life, or whether this further requires some external condition; whether the virtuous and wise may also be happy on the rack and the wheel, or in the bull of Phalaris; or whether it does not go as far as this. For certainly this would be the touchstone of an ethical system of this kind; the practice of it must give happiness directly and unconditionally. If it cannot do this it does not accomplish what it ought, and must be rejected. It is therefore with truth and in accordance with the Christian point of view that Augustine prefaces his exposition of the moral systems of the ancients (*De Civ. Dei*, Lib. xix. c. 1) with the explanation: "*Exponenda sunt nobis argumenta mortalium, quibus sibi ipsi beatitudinem*

facere in hujus vitæ infelicitate *moliti sunt; ut ab eorum rebus vanis spes nostra quid differat clarescat. De finibus bonorum et malorum multa inter se philosophi disputarunt; quam quæstionem maxima intentione versantes, invenire conati sunt, quid efficiat hominem beatum: illud enim est finis bonorum.*" I wish to place beyond all doubt the eudæmonistic end which we have ascribed to all ancient ethics by several express statements of the ancients themselves. Aristotle says in the "*Eth. Magna*," i. 4: "Ἡ ευδαιμονια εν τῳ εν ζῃν εστι, το δε ευ ζῃν εν τῳ κατα τας αρετας ζῃν." (*Felicitas in bene vivendo posita est: verum bene vivere est in eo positum, ut secundum virtutem vivamus*), with which may be compared "*Eth. Nicom.*," i. 5. "*Cic. Tusc.*," v. 1: "*Nam, quum ea causa impulerit eos, qui primi se ad philosophiæ studia contulerunt, ut, omnibus rebus posthabitis, totos se in optimo vitæ statu exquirendo collocarent; profecto spe beate vivendi tantam in eo studio curam operamque posuerunt*". According to Plutarch (*De Repugn. Stoic.*, c. xviii.) Chrysippus said: "Το κατα κακιαν ζῃν τῳ κακοδαιμονως ζῃν ταυτον εστι." (*Vitiose vivere idem est guod vivere infeliciter.*) Ibid., c. 26: "Ἡ φρονησις ουχ ἑτερον εστι της ευδαιμονιας καθ᾽ ἑαυτο, αλλ᾽ ευδαιμονια." (*Prudentia nihil differt a felicitate, estque ipsa adeo felicitas.*) "Stob. Ecl.," Lib. ii. c. 7: "Τελος δε φασιν ειναι το ευδαιμονειν, ὁυ ἑνεκα παντα πραττεται." (*Finem esse dicunt felicitatem, cujus causa fiunt omnia.*) "Ευδαιμονιαν συνωνυμειν τῳ τελει λεγουσι." (*Finem bonorum et felicitatem synonyma esse dicunt.*) "Arrian Diss. Epict.," i. 4: "Ἡ αρετη ταυτην εχει την επαγγελιαν, ευδαιμονιαν ποιησαι." (*Virtus profitetur, se felicitatem præstare.*) Sen., Ep. 90: "*Ceterum (sapientia) ad beatum statum tendit, illo ducit, illo vias aperit.*" — Id., Ep. 108: "*Illud admoneo auditionem philosophorum, lectionemque, ad propositum beatæ vitæ trahendum.*"

The ethics of the Cynics also adopted this end of the happiest life, as the Emperor Julian expressly testifies (Orat. vi.): "Της Κυνικης δε φιλοσοφιας σκοπος μεν εστι και τελος, ὡσπερ δη και πασης φιλοσοφιας, το ευδαιμονειν; το δε ευδαιμονειν εν τῳ ζῃν κατα φυσιν, αλλα μη προς τας των πολλων δοξας." (*Cynicæ philosophiæ ut etiam omnis philosophiæ, scopus et finis est feliciter vivere: felicitas vitæ autem in eo posita est, ut secundum naturam vivatur, nec vero secundum opiniones multitudinis.*) Only the Cynics followed quite a peculiar path to this end, a path directly

opposed to the ordinary one — the path of extreme privation. They start from the insight that the motions of the will which are brought about by the objects which attract and excite it, and the wearisome, and for the most part vain, efforts to attain these, or, if they are attained, the fear of losing them, and finally the loss itself, produce far greater pain than the want of all these objects ever can. Therefore, in order to attain to the life that is most free from pain, they chose the path of the extremest destitution, and fled from all pleasures as snares through which one was afterwards handed over to pain. But after this they could boldly scorn happiness and its caprices. This is the *spirit of cynicism*. Seneca distinctly expresses it in the eighth chapter, "*De Tranquilitate Animi*:" "*Cogitandum est, quanto levior dolor sit, non habere, quam perdere: et intelligemus paupertati eo minorem tormentorum, quo minorem damnorum esse materiam.*" Then: "*Tolerabilius est, faciliusque, non acquirere, quam amittere.... Diogenes effecit, ne quid sibi eripi posset, ... qui se fortuitis omnibus exuit.... Videtur mihi dixisse; age tuum negotium, fortuna: nihil apud Diogenem jam tuum est.*" The parallel passage to this last sentence is the quotation of Stobæus (*Ecl.* ii. 7): "Διογενης εφη νομιζειν ὁραν την Τυχην ενορωσαν αυτον και λεγουσαν; τουτον δ᾽ ου δυναμαι βαλεειν κυνα λυσσητηρα." (*Diogenes credere se dixit, videre Fortunam, ipsum intuentem, ac dicentem: aut hunc non potui tetigisse canem rabiosum.*) The same spirit of cynicism is also shown in the epitaph on Diogenes, in Suidas, under the word Φιλισκος, and in "Diogenes Laertius," vi. 2:

"Γηρασκει μεν χαλκος ὑπο χρονου; αλλα σον ουτι
Κυδος ὁ πας αιων, Διογενης, καθελει;
Μουνος επει βιοτης αυταρκεα δοξαν εδειξας
Θνητοις, και ζωης οιμον ελαφροτατην."

(*Æra quidem absumit tempus, sed tempore numquam
Interitura tua est gloria, Diogenes:
Quandoquidem ad vitam miseris mortalibus æquam
Monstrata est facilis, te duce, et ampla via.*)

Accordingly the fundamental thought of cynicism is that life in its simplest and nakedest form, with the hardships that belong to it by nature, is the most endurable, and is therefore to be chosen; for every assistance, convenience, gratification, and pleasure by means of which men seek to make life more agreeable only brings with it new and greater ills than

originally belonged to it. Therefore we may regard the following sentence as the expression of the kernel of the doctrine of cynicism: “Διογενης εβοᾳ πολλακις λεγων, τον των ανθωπων βιον ραδιον ὑπο των θεων δεδοσθαι, αποκεκρυφθαι δε αυτον ζητουντων μελιπηκτα και μυρα και τα παραπλησια.” (*Diogenes clamabat sæpius, hominum vitam facilem a diis dari, verum occultari illam quœrentibus mellita cibaria, unguenta et his similia.*) (*Diog., Laert.*, vi. 2.) And further: “Δεον, αντι των αχρηστων πονων, τους κατα φυσιν ἑλομενους, ζῃν ευδαιμονως; παρα την ανοιαν κακοδαιμονουσι.... τον αυτον χαρακτηρα του βιου λεγων διεξαγειν, ὁνπερ και Ἡρακλης, μηδεν ελευθηριας προκρινων.” (*Quum igitur, repudiatis inutilibus laboribus, naturales insequi, ac vivere beate debeamus, per summam dementiam infelices sumus.... eandem vitæ formam, quam Hercules, se vivere affirmans, nihil libertati præferens. Ibid.*) Therefore the old, genuine Cynics, Antisthenes, Diogenes, Krates, and their disciples had once for all renounced every possession, all conveniences and pleasures, in order to escape for ever from the troubles and cares, the dependence and the pains, which are inevitably bound up with them and are not counterbalanced by them. Through the bare satisfaction of the most pressing wants and the renunciation of everything superfluous they thought they would come off best. Accordingly they contented themselves with what in Athens or Corinth was to be had almost for nothing, such as lupines, water, an old threadbare cloak, a wallet, and a staff. They begged occasionally, as far as was necessary to supply such wants, but they never worked. Yet they accepted absolutely nothing that exceeded the wants referred to above. Independence in the widest sense was their aim. They occupied their time in resting, going about, talking with all men, and much mocking, laughing, and joking; their characteristic was carelessness and great cheerfulness. Since now in this manner of life they had no aims of their own, no purposes or ends to pursue, thus were lifted above the sphere of human action, and at the same time always enjoyed complete leisure, they were admirably fitted, as men of proved strength of mind, to be the advisers and admonishers of the rest. Therefore Apuleius says (*Florid.*, iv.): “*Crates, ut lar familiaris apud homines suæ ætatis cultus est. Nulla domus ei unquam clausa erat: nec erat patrisfamilias tam absconditum secretum, quin eo tempestive Crates interveniret, litium omnium et jurgiorum inter propinquos disceptator et arbiter.*” Thus in this, as in so many other respects, they show

a great likeness to the mendicant friars of modern times, that is, to the better and more genuine among them, whose ideal may be seen in the Capucine Christoforo in Manzoni's famous romance. Yet this resemblance lies only in the effects, not in the cause. They agree in the result, but the fundamental thought of the two is quite different. With the friars, as with the Sannyâsis, who are akin to them, it is an aim which transcends life; but with the Cynics it is only the conviction that it is easier to reduce their wishes and their wants to the *minimum*, than to attain to the *maximum* in their satisfaction, which indeed is impossible, for with their satisfaction the wishes and wants grow *ad infinitum*; therefore, in order to reach the goal of all ancient ethics, the greatest happiness possible in this life, they took the path of renunciation as the shortest and easiest: "ὀθεν και τον Κυνισμον ειρηκασιν συντομον επ᾽ αρετην ὀδον." (*Unde Cynismum dixere compendiosam ad virtutem viam.*) *Diog. Laert.*, vi. 9. The fundamental difference between the spirit of cynicism and that of asceticism comes out very clearly in the humility which is essential to the ascetic, but is so foreign to the Cynic that, on the contrary, he is distinguished beyond everything else for pride and scorn: —

"*Sapiens uno minor est Jove, dives,*
Liber, honoratus, pulcher, rex denique regum." — *Hor.*

On the other hand, the view of life held by the Cynics agrees in spirit with that of J. J. Rousseau as he expounds it in the "*Discours sur l'Origine de l'Inégalité*." For he also would wish to lead us back to the crude state of nature, and regards the reduction of our wants to the minimum as the surest path to happiness. For the rest, the Cynics were exclusively *practical* philosophers: at least no account of their theoretical philosophy is known to me.

Now the Stoics proceeded from them in this way — they changed the practical into the theoretical. They held that the *actual* dispensing with everything that can be done without is not demanded, but that it is sufficient that we should regard possessions and pleasures constantly as *dispensable*, and as held in the hand of chance; for then the actual deprivation of them, if it should chance to occur, would neither be unexpected nor fall heavily. One might always have and enjoy everything; only one must ever keep present the conviction of the worthlessness and dispensableness of these good things on the one hand, and of their uncertainty and perishableness on the other, and therefore prize them all very little, and be always ready to give

them up. Nay more, he who must actually dispense with these things in order not to be moved by them, thereby shows that in his heart he holds them to be truly good things, which one must put quite out of sight if one is not to long after them. The wise man, on the other hand, knows that they are not good things at all, but rather perfectly indifferent things, αδιαφορα, in any case προηγμενα. Therefore if they present themselves he will accept them, but yet is always ready to let them go again, if chance, to which they belong, should demand them back; for they are των ουκ εφ᾽ ἡμιν. In this sense, Epictetus, chap. vii., says that the wise man, like one who has landed from a ship, &c., will also let himself be comforted by a wife or a child, but yet will always be ready, whenever the captain calls, to let them go again. Thus the Stoics perfected the theory of equanimity and independence at the cost of the practice, for they reduced everything to a mental process, and by arguments, such as are presented in the first chapter of Epictetus, sophisticated themselves into all the amenities of life. But in doing so they left out of account that everything to which one is accustomed becomes a need, and therefore can only be given up with pain; that the will does not allow itself to be played with, cannot enjoy without loving the pleasures; that a dog does not remain indifferent if one draws a piece of meat through its mouth, and neither does a wise man if he is hungry; and that there is no middle path between desiring and renouncing. But they believed that they satisfied their principles if, sitting at a luxurious Roman table, they left no dish untasted, yet at the same time protested that they were each and all of them mere προηγμενα, not αγαθα; or in plain English, if they eat, drank, and were merry, yet gave no thanks to God for it all, but rather made fastidious faces, and persisted in boldly asserting that they gained nothing whatever from the whole feast. This was the expedient of the Stoics; they were therefore mere braggarts, and stand to the Cynics in much the same relation as well-fed Benedictines and Augustines stand to Franciscans and Capucines. Now the more they neglected practice, the more they refined the theory. I shall here add a few proofs and supplementary details to the exposition of it given at the close of our first book.

If we search in the writings of the Stoics which remain to us, all of which are unsystematically composed, for the ultimate ground of that irrefragible equanimity which is unceasingly demanded of us, we find no other than the knowledge that the course of the world is entirely independent of our will, and consequently, that the evil which befalls us is inevitable. If we have

regulated our claims by a correct insight into this, then mourning, rejoicing, fearing, and hoping are follies of which we are no longer capable. Further, especially in the commentaries of Arrian, it is surreptitiously assumed that all that is ουκ εφ᾽ ἡμιν (*i.e.*, does not depend upon us) is at once also ου προς ἡμας (*i.e.*, does not concern us). Yet it remains true that all the good things of life are in the power of chance, and therefore whenever it makes use of this power to deprive us of them, we are unhappy if we have placed our happiness in them. From this unworthy fate we are, in the opinion of the Stoics, delivered by the right use of reason, by virtue of which we regard all these things, never as ours, but only as lent to us for an indefinite time; only thus can we never really lose them. Therefore Seneca says (Ep. 98): "*Si, quid humanarum rerum varietas possit, cogitaverit, ante quam senserit*," and Diogenes Laertius (vii. 1. 87): "Ισον δε εστι το κατ᾽ αρετην ζῃν τῳ κατ᾽ εμπειριαν των φυσει συμβαινοντων ζῃν." (*Secundum virtutem vivere idem est, quod secundum experientiam eorum, quæ secundum naturam accidunt, vivere.*) The passage in Arrian's "Discourses of Epictetus," B. iii., c. 24, 84-89, is particularly in point here; and especially, as a proof of what I have said in this reference in § 16 of the first volume, the passage: "Τουτο γαρ εστι το αιτιον τοις ανθροποις παντων των κακων το τας προληψεις τας κοινας μη δυνασθαι εφαρμοζειν τοις επι μερους," Ibid. iv., 1. 42. (*Hæc enim causa est hominibus omnium malorum, quod anticipationes generales rebus singularibus accommodare non possunt.*) Similarly the passage in "Marcus Aurelius" (iv. 29): "Ει ξενος κοσμου ὁ μη γνωριζων τα εν αυτῳ οντα, ουχ ἡττον ξενος και ο μη γνωριζων τα γιγνομενα;" that is: "If he is a stranger to the universe who does not know what is in it, no less is he a stranger who does not know how things go on in it." Also Seneca's eleventh chapter, "*De Tranquilitate Animi*," is a complete proof of this view. The opinion of the Stoics amounts on the whole to this, that if a man has watched for a while the juggling illusion of happiness and then uses his reason, he must recognise both the rapid changes of the dice and the intrinsic worthlessness of the counters, and therefore must henceforth remain unmoved. Taken generally the Stoical point of view may be thus expressed: our suffering always arises from the want of agreement between our wishes and the course of the world. Therefore one of these two must be changed and adapted to the other. Since now the course of things is not in our power (ουκ εφ᾽ ἡμιν), we must direct our volitions and desires according to the course

of things: for the will alone is εφ᾽ ἡμιν. This adaptation of volition to the course of the external world, thus to the nature of things, is very often understood under the ambiguous κατα φυσιν ζην. See the "Discourses of Epictetus," ii. 17, 21, 22. Seneca also denotes this point of view (Ep. 119) when he says: "*Nihil interest, utrum non desideres, an habeas. Summa rei in utroque est eadem: non torqueberis.*" Also Cicero (*Tusc.* iv. 26) by the words: "*Solum habere velle, summa dementia est.*" Similarly Arrian (iv. 1. 175): "Ου γαρ εκπληρωσει των επιθυμουμενων ελευθερια παρασκευαζεται, αλλα ανασκευη της επιθυμιας." (*Non enim explendis desideriis libertas comparatur, sed tollenda cupiditate.*)

The collected quotations in the "*Historia Philosophiæ Græco-Romanæ*" of Ritter and Preller may be taken as proofs of what I have said, in the place referred to above, about the ὁμολογουμενως ζῃν of the Stoics. Also the saying of Seneca (Ep. 31, and again Ep. 74): "*Perfecta virtus est æqualitas et tenor vitæ per omnia consonans sibi.*" The following passage of Seneca's indicates the spirit of the Stoa generally (Ep. 92): "*Quid est beata vita? Securitas et perpetua tranquillitas. Hanc dabit animi magnitudo, dabit constantia bene judicati tenax.*" A systematical study of the Stoics will convince every one that the end of their ethics, like that of the ethics of Cynicism from which they sprang, is really nothing else than a life as free as possible from pain, and therefore as happy as possible. Whence it follows that the Stoical morality is only a special form of *Eudæmonism*. It has not, like the Indian, the Christian, and even the Platonic ethics, a metaphysical tendency, a transcendental end, but a completely immanent end, attainable in this life; the steadfast serenity (αταραξια) and unclouded happiness of the wise man, whom nothing can disturb. Yet it cannot be denied that the later Stoics, especially Arrian, sometimes lose sight of this end, and show a really ascetic tendency, which is to be attributed to the Christian and Oriental spirit in general which was then already spreading. If we consider closely and seriously the goal of Stoicism, that αταραξια, we find in it merely a hardening and insensibility to the blow of fate which a man attains to because he keeps ever present to his mind the shortness of life, the emptiness of pleasure, the instability of happiness, and has also discerned that the difference between happiness and unhappiness is very much less than our anticipation of both is wont to represent. But this is yet no state of happiness; it is only the patient endurance of sufferings which one has

foreseen as irremediable. Yet magnanimity and worth consist in this, that one should bear silently and patiently what is irremediable, in melancholy peace, remaining always the same, while others pass from rejoicing to despair and from despair to rejoicing. Accordingly one may also conceive of Stoicism as a spiritual hygiene, in accordance with which, just as one hardens the body against the influences of wind and weather, against fatigue and exertion, one has also to harden one's mind against misfortune, danger, loss, injustice, malice, perfidy, arrogance, and the folly of men.

I remark further, that the καθγκοντα of the Stoics, which Cicero translates *officia*, signify as nearly as possible *Obliegenheiten*, or that which it befits the occasion to do; English, *incumbencies*; Italian, *quel che tocca a me di fare, o di lasciare*, thus what *it behoves* a reasonable man to do. Cf. *Diog. Laert.*, vii. 1. 109. Finally, the *pantheism* of the Stoics, though absolutely inconsistent with many an exhortation of Arrian, is most distinctly expressed by Seneca: "*Quid est Deus? Mens universi. Quid est Deus? Quod vides totum, et quod non vides totum. Sic demum magnitudo sua illi redditur, qua nihil majus excogitari potest: si solus est omnia, opus suum et extra, et intra tenet.*" (*Quæst. Natur.* 1, *præfatio* 12.)

Chapter XVII.[27] On Man's Need Of Metaphysics.

With the exception of man, no being wonders at its own existence; but it is to them all so much a matter of course that they do not observe it. The wisdom of nature speaks out of the peaceful glance of the brutes; for in them the will and the intellect are not yet so widely separated that they can be astonished at each other when they meet again. Thus here the whole phenomenon is still firmly attached to the stem of nature from which it has come, and is partaker of the unconscious omniscience of the great mother. Only after the inner being of nature (the will to live in its objectification) has ascended, vigorous and cheerful, through the two series of unconscious existences, and then through the long and broad series of animals, does it attain at last to reflection for the first time on the entrance of reason, thus in man. Then it marvels at its own works, and asks itself what it itself is. Its wonder however is the more serious, as it here stands for the first time consciously in the presence of *death*, and besides the finiteness of all existence, the vanity of all effort forces itself more or less upon it. With this reflection and this wonder there arises therefore for man alone, the *need for a metaphysic*; he is accordingly an *animal metaphysicum*. At the beginning of his consciousness certainly he also accepts himself as a matter of course. This does not last long however, but very early, with the first dawn of reflection, that wonder already appears, which is some day to become the mother of metaphysics. In agreement with this Aristotle also says at the beginning of his metaphysics: “Δια γαρ το θαυμαζειν οἱ ανθρωποι και νυν και το πρωτον ηρξαντο φιλοσοφειν.” (*Propter admirationem enim et nunc et primo inceperunt homines philosophari.*) Moreover, the special philosophical disposition consists primarily in this, that a man is capable of wonder beyond the ordinary and everyday degree, and is thus induced to make the *universal* of the phenomenon his problem, while the investigators in the natural sciences wonder only at exquisite or rare phenomena, and their problem is merely to refer these to phenomena which are better known. The lower a man stands in an intellectual regard the less of a problem is existence itself for him; everything, how it is, and that it is, appears to him rather a matter of course. This rests upon the fact that his intellect still remains perfectly true to its original destiny of being serviceable to the will as the medium of motives, and therefore is closely

bound up with the world and nature, as an integral part of them. Consequently it is very far from comprehending the world in a purely objective manner, freeing itself, so to speak, from the whole of things, opposing itself to this whole, and so for a while becoming as if self-existent. On the other hand, the philosophical wonder which springs from this is conditioned in the individual by higher development of the intellect, yet in general not by this alone; but without doubt it is the knowledge of death, and along with this the consideration of the suffering and misery of life, which gives the strongest impulse to philosophical reflection and metaphysical explanation of the world. If our life were endless and painless, it would perhaps occur to no one to ask why the world exists, and is just the kind of world it is; but everything would just be taken as a matter of course. In accordance with this we find that the interest which philosophical and also religious systems inspire has always its strongest hold in the dogma of some kind of existence after death; and although the most recent systems seem to make the existence of their gods the main point, and to defend this most zealously, yet in reality this is only because they have connected their special dogma of immortality with this, and regard the one as inseparable from the other: only on this account is it of importance to them. For if one could establish their doctrine of immortality for them in some other way, their lively zeal for their gods would at once cool, and it would give place almost to complete indifference if, conversely, the absolute impossibility of immortality were proved to them; for the interest in the existence of the gods would vanish with the hope of a closer acquaintance with them, to the residuum which might connect itself with their possible influence on the events of this present life. But if one could prove that continued existence after death is incompatible with the existence of gods, because, let us say, it pre-supposes originality of being, they would soon sacrifice the gods to their own immortality and become zealous for Atheism. The fact that the materialistic systems, properly so-called, and also absolute scepticism, have never been able to obtain a general or lasting influence, depends upon the same grounds.

Temples and churches, pagodas and mosques, in all lands and in all ages, in splendour and vastness, testify to the metaphysical need of man, which, strong and ineradicable, follows close upon his physical need. Certainly whoever is satirically inclined might add that this metaphysical need is a modest fellow who is content with poor fare. It sometimes allows itself to

be satisfied with clumsy fables and insipid tales. If only imprinted early enough, they are for a man adequate explanations of his existence and supports of his morality. Consider, for example, the Koran. This wretched book was sufficient to found a religion of the world, to satisfy the metaphysical need of innumerable millions of men for twelve hundred years, to become the foundation of their morality, and of no small contempt for death, and also to inspire them to bloody wars and most extended conquests. We find in it the saddest and the poorest form of Theism. Much may be lost through the translations; but I have not been able to discover one single valuable thought in it. Such things show that metaphysical capacity does not go hand in hand with the metaphysical need. Yet it will appear that in the early ages of the present surface of the earth this was not the case, and that those who stood considerably nearer than we do to the beginning of the human race and the source of organic nature, had also both greater energy of the intuitive faculty of knowledge, and a truer disposition of mind, so that they were capable of a purer, more direct comprehension of the inner being of nature, and were thus in a position to satisfy the metaphysical need in a more worthy manner. Thus originated in the primitive ancestors of the Brahmans, the Rishis, the almost super-human conceptions which were afterwards set down in the Upanishads of the Vedas.

On the other hand, there have never been wanting persons who were interested in deriving their living from that metaphysical need, and in making the utmost they could out of it. Therefore among all nations there are monopolists and farmers-general of it — the priests. Yet their trade had everywhere to be assured to them in this way, that they received the right to impart their metaphysical dogmas to men at a very early age, before the judgment has awakened from its morning slumber, thus in early childhood; for then every well-impressed dogma, however senseless it may be, remains for ever. If they had to wait till the judgment is ripe, their privileges could not continue.

A second, though not a numerous class of persons, who derive their support from the metaphysical need of man, is constituted by those who live by *philosophy*. By the Greeks they were called Sophists, by the moderns they are called Professors of Philosophy. Aristotle (*Metaph.*, ii. 2) without hesitation numbers Aristippus among the Sophists. In Diogenes Laertius (ii. 65) we find that the reason of this is that he was the first of the Socratics

who accepted payment for his philosophy; on account of which Socrates also returned him his present. Among the moderns also those who live *by* philosophy are not only, as a rule, and with the rarest exceptions, quite different from those who live *for* philosophy, but they are very often the opponents, the secret and irreconcilable enemies of the latter. For every true and important philosophical achievement will overshadow their own too much, and, moreover, cannot adapt itself to the views and limitations of their guild. Therefore it is always their endeavour to prevent such a work from making its way; and for this purpose, according to the age and circumstances in each case, the customary means are suppressing, concealing, hushing up, ignoring and keeping secret, or denying, disparaging, censuring, slandering and distorting, or, finally, denouncing and persecuting. Hence many a great man has had to drag himself wearily through life unknown, unhonoured, unrewarded, till at last, after his death, the world became undeceived as to him and as to them. In the meanwhile they had attained their end, had been accepted by preventing him from being accepted, and, with wife and child, had lived *by* philosophy, while he lived *for* it. But if he is dead, then the thing is reversed; the new generation of the former class, which always exists, now becomes heir to his achievements, cuts them down to its own measure, and now lives *by* him. That Kant could yet live both *by* and *for* philosophy depended on the rare circumstance that, for the first time since *Divus Antoninus* and *Divus Julianus*, a philosopher sat on the throne. Only under such auspices could the "Critique of Pure Reason" have seen the light. Scarcely was the king dead than we see that Kant also, seized with fear, because he belonged to the guild, modified, expurgated, and spoiled his masterpiece in the second edition, and yet was soon in danger of losing his place; so that Campe invited him to come to him, in Brunswick, and live with him as the instructor of his family (Ring., *Ansichten aus Kant's Leben*, p. 68). University philosophy is, as a rule, mere juggling. Its real aim is to impart to the students, in the deepest ground of their thought, that tendency of mind which the ministry that appoints to the professorships regards as consistent with its views. The ministry may also be perfectly right in this from a statesman's point of view; only the result of it is that such philosophy of the chair is a *nervis alienis mobile lignum*, and cannot be regarded as serious philosophy, but as the mere jest of it. Moreover, it is at any rate just that such inspection or guidance should extend only to the

philosophy of the chair, and not to the real philosophy that is in earnest. For if anything in the world is worth wishing for — so well worth wishing for that even the ignorant and dull herd in its more reflective moments would prize it more than silver and gold — it is that a ray of light should fall on the obscurity of our being, and that we should gain some explanation of our mysterious existence, in which nothing is clear but its misery and its vanity. But even if this is in itself attainable, it is made impossible by imposed and compulsory solutions.

We shall now subject to a general consideration the different ways of satisfying this strong metaphysical need.

By *metaphysics* I understand all knowledge that pretends to transcend the possibility of experience, thus to transcend nature or the given phenomenal appearance of things, in order to give an explanation of that by which, in some sense or other, this experience or nature is conditioned; or, to speak in popular language, of that which is behind nature, and makes it possible. But the great original diversity in the power of understanding, besides the cultivation of it, which demands much leisure, makes so great a difference between men, that as soon as a people has emerged from the state of savages, no *one* metaphysic can serve for them all. Therefore among civilised nations we find throughout two different kinds of metaphysics, which are distinguished by the fact that the one has its evidence *in itself*, the other *outside itself*. Since the metaphysical systems of the first kind require reflection, culture, and leisure for the recognition of their evidence, they can be accessible only to a very small number of men; and, moreover, they can only arise and maintain their existence in the case of advanced civilisation. On the other hand, the systems of the second kind exclusively are for the great majority of men who are not capable of thinking, but only of believing, and who are not accessible to reasons, but only to authority. These systems may therefore be called metaphysics of the people, after the analogy of poetry of the people, and also wisdom of the people, by which is understood proverbs. These systems, however, are known under the name of religions, and are found among all nations, not excepting even the most savage. Their evidence is, as has been said, external, and as such is called revelation, which is authenticated by signs and miracles. Their arguments are principally threats of eternal, and indeed also temporal evils, directed against unbelievers, and even against mere doubters. As *ultima ratio theologorum*, we find among many nations the stake or things similar to it.

If they seek a different authentication, or if they make use of other arguments, they already make the transition into the systems of the first kind, and may degenerate into a mixture of the two, which brings more danger than advantage, for their invaluable prerogative of being imparted to *children* gives them the surest guarantee of the permanent possession of the mind, for thereby their dogmas grow into a kind of second inborn intellect, like the twig upon the grafted tree; while, on the other hand, the systems of the first kind only appeal to grown-up people, and in them always find a system of the second kind already in possession of their convictions. Both kinds of metaphysics, whose difference may be briefly expressed by the words reasoned conviction and faith, have this in common, that every one of their particular systems stands in a hostile relation to all the others of its kind. Between those of the first kind war is waged only with word and pen; between those of the second with fire and sword as well. Several of the latter owe their propagation in part to this last kind of polemic, and all have by degrees divided the earth between them, and indeed with such decided authority that the peoples of the earth are distinguished and separated more according to them than according to nationality or government. They alone *reign*, each in its own province. The systems of the first kind, on the contrary, are at the most *tolerated*, and even this only because, on account of the small number of their adherents, they are for the most part not considered worth the trouble of combating with fire and sword — although, where it seemed necessary, these also have been employed against them with effect; besides, they occur only in a sporadic form. Yet in general they have only been endured in a tamed and subjugated condition, for the system of the second kind which prevailed in the country ordered them to conform their teaching more or less closely to its own. Sometimes it not only subjugated them, but even employed their services and used them as a support, which is however a dangerous experiment. For these systems of the first kind, since they are deprived of power, believe they may advance themselves by craft, and never entirely lay aside a secret ill-will which at times comes unexpectedly into prominence and inflicts injuries which are hard to heal. For they are further made the more dangerous by the fact that all the real sciences, not even excepting the most innocent, are their secret allies against the systems of the second kind, and without themselves being openly at war with the latter, suddenly and unexpectedly do great mischief in their province. Besides, the attempt which is aimed at by the enlistment

referred to of the services of the systems of the first kind by the second — the attempt to add an inner authentication to a system whose original authentication was external, is in its nature perilous; for, if it were capable of such an authentication, it would never have required an external one. And in general it is always a hazardous thing to attempt to place a new foundation under a finished structure. Moreover, how should a religion require the suffrage of a philosophy? It has everything upon its side — revelation, tradition, miracles, prophecies, the protection of the government, the highest rank, as is due to the truth, the consent and reverence of all, a thousand temples in which it is proclaimed and practised, bands of sworn priests, and, what is more than all, the invaluable privilege of being allowed to imprint its doctrines on the mind at the tender age of childhood, whereby they became almost like innate ideas. With such wealth of means at its disposal, still to desire the assent of poor philosophers it must be more covetous, or to care about their contradiction it must be more fearful, than seems to be compatible with a good conscience.

To the distinction established above between metaphysics of the first and of the second kind, we have yet to add the following: — A system of the first kind, thus a philosophy, makes the claim, and has therefore the obligation, in everything that it says, *sensu stricto et proprio*, to be true, for it appeals to thought and conviction. A religion, on the other hand, being intended for the innumerable multitude who, since they are incapable of examination and thought, would never comprehend the profoundest and most difficult truths *sensu proprio*, has only the obligation to be true *sensu allegorico*. Truth cannot appear naked before the people. A symptom of this *allegorical* nature of religions is the *mysteries* which are to be found perhaps in them all, certain dogmas which cannot even be distinctly thought, not to speak of being literally true. Indeed, perhaps it might be asserted that some absolute contradictions, some actual absurdities, are an essential ingredient in a complete religion, for these are just the stamp of its allegorical nature, and the only adequate means of making the ordinary mind and the uncultured understanding *feel* what would be incomprehensible to it, that religion has ultimately to do with quite a different order of things, with an order of *things in themselves*, in the presence of which the laws of this phenomenal world, in conformity with which it must speak, vanish; and that therefore not only the contradictory but also the comprehensible dogmas are really only allegories and

accommodations to the human power of comprehension. It seems to me that it was in this spirit that Augustine and even Luther adhered to the mysteries of Christianity in opposition to Pelagianism, which sought to reduce everything to the dull level of comprehensibility. From this point of view it is also conceivable how Tertullian could say in all seriousness: "*Prorsus credibile est, quia ineptum est: ... certum est, quia impossibile*" (*De Carne Christi*, c. 5). This *allegorical* nature of religions makes them independent of the proofs which are incumbent on philosophy, and in general withdraws them from investigation. Instead of this they require faith, that is, a voluntary admission that such is the state of the case. Since, then, faith guides action, and the allegory is always so framed that, as regards the practical, it leads precisely to that which the truth *sensu proprio* would also lead to, religion is justified in promising to those who believe eternal salvation. Thus we see that in the main, and for the great majority, who cannot apply themselves to thought, religions very well supply the place of metaphysics in general, the need of which man feels to be imperative. They do this partly in a practical interest, as the guiding star of their action, the unfurled standard of integrity and virtue, as Kant admirably expresses it; partly as the indispensable comfort in the heavy sorrows of life, in which capacity they fully supply the place of an objectively true metaphysic, because they lift man above himself and his existence in time, as well perhaps as such a metaphysic ever could. In this their great value and indeed necessity shows itself very clearly. For Plato says, and says rightly, "φιλόσοφον πλῆθος ἀδύνατον εἶναι" (*vulgus philosophum esse impossible est*. *De Rep.*, vi. p. 89, *Bip*.) On the other hand, the only stumbling-stone is this, that religions never dare to confess their allegorical nature, but have to assert that they are true *sensu proprio*. They thereby encroach on the province of metaphysics proper, and call forth the antagonism of the latter, which has therefore expressed itself at all times when it was not chained up. The controversy which is so perseveringly carried on in our own day between supernaturalists and rationalists also rests on the failure to recognise the allegorical nature of all religion. Both wish to have Christianity true *sensu proprio*; in this sense the former wish to maintain it without deduction, as it were with skin and hair; and thus they have a hard stand to make against the knowledge and general culture of the age. The latter wish to explain away all that is properly Christian; whereupon they retain something which is neither *sensu proprio* nor *sensu allegorico* true,

but rather a mere platitude, little better than Judaism, or at the most a shallow Pelagianism, and, what is worst, an abject optimism, absolutely foreign to Christianity proper. Moreover, the attempt to found a religion upon reason removes it into the other class of metaphysics, that which has its authentication *in itself*, thus to the foreign ground of the philosophical systems, and into the conflict which these wage against each other in their own arena, and consequently exposes it to the light fire of scepticism and the heavy artillery of the "Critique of Pure Reason;" but for it to venture there would be clear presumption.

It would be most beneficial to both kinds of metaphysics that each of them should remain clearly separated from the other and confine itself to its own province, that it may there be able to develop its nature fully. Instead of which, through the whole Christian era, the endeavour has been to bring about a fusion of the two, for the dogmas and conceptions of the one have been carried over into the other, whereby both are spoiled. This has taken place in the most open manner in our own day in that strange hermaphrodite or centaur, the so-called philosophy of religion, which, as a kind of gnosis, endeavours to interpret the given religion, and to explain what is true *sensu allegorico* through something which is true *sensu proprio*. But for this we would have to know and possess the truth *sensu proprio* already; and in that case such an interpretation would be superfluous. For to seek first to find metaphysics, *i.e.*, the truth *sensu proprio*, merely out of religion by explanation and interpretation would be a doubtful and dangerous undertaking, to which one would only make up one's mind if it were proved that truth, like iron and other base metals, could only be found in a mixed, not in a pure form, and therefore one could only obtain it by reduction from the mixed ore.

Religions are necessary for the people, and an inestimable benefit to them. But if they oppose themselves to the progress of mankind in the knowledge of the truth, they must with the utmost possible forbearance be set aside. And to require that a great mind — a Shakspeare; a Goethe — should make the dogmas of any religion implicitly, *bonâ fide et sensu proprio*, his conviction is to require that a giant should put on the shoe of a dwarf.

Religions, being calculated with reference to the power of comprehension of the great mass of men, can only have indirect, not immediate truth. To require of them the latter is as if one wished to read the

letters set up in the form-chase, instead of their impression. The value of a religion will accordingly depend upon the greater or less content of truth which it contains under the veil of allegory, and then upon the greater or less distinctness with which it becomes visible through this veil, thus upon the transparency of the latter. It almost seems that, as the oldest languages are the most perfect, so also are the oldest religions. If I were to take the results of my philosophy as the standard of truth, I would be obliged to concede to Buddhism the pre-eminence over the rest. In any case it must be a satisfaction to me to see my teaching in such close agreement with a religion which the majority of men upon the earth hold as their own; for it numbers far more adherents than any other. This agreement, however, must be the more satisfactory to me because in my philosophising I have certainly not been under its influence. For up till 1818, when my work appeared, there were very few, exceedingly incomplete and scanty, accounts of Buddhism to be found in Europe, which were almost entirely limited to a few essays in the earlier volumes of "Asiatic Researches," and were principally concerned with the Buddhism of the Burmese. Only since then has fuller information about this religion gradually reached us, chiefly through the profound and instructive essays of the meritorious member of the St. Petersburg Academy, J. J. Schmidt, in the proceedings of his Academy, and then little by little through several English and French scholars, so that I was able to give a fairly numerous list of the best works on this religion in my work, "*Ueber den Willen in der Natur*," under the heading *Sinologie*. Unfortunately Csoma Körösi, that persevering Hungarian, who, in order to study the language and sacred writings of Buddhism, spent many years in Tibet, and for the most part in Buddhist monasteries, was carried off by death just as he was beginning to work out for us the results of his researches. I cannot, however, deny the pleasure with which I read, in his provisional accounts, several passages cited directly from the Kahgyur itself; for example, the following conversation of the dying Buddha with Brahma, who is doing him homage: "There is a description of their conversation on the subject of creation, — by whom was the world made? Shakya asks several questions of Brahma, — whether was it he who made or produced such and such things, and endowed or blessed them with such and such virtues or properties, — whether was it he who caused the several revolutions in the destruction and regeneration of the world. He denies that he had ever done anything to that effect. At last he

himself asks Shakya how the world was made, — by whom? Here are attributed all changes in the world to the moral works of the animal beings, and it is stated that in the world all is illusion, there is no reality in the things; all is empty. Brahma, being instructed in his doctrine, becomes his follower" (Asiatic Researches, vol. xx. p. 434).

I cannot place, as is always done, the fundamental difference of all religions in the question whether they are monotheistic, polytheistic, pantheistic, or atheistic, but only in the question whether they are optimistic or pessimistic, that is, whether they present the existence of the world as justified by itself, and therefore praise and value it, or regard it as something that can only be conceived as the consequence of our guilt, and therefore properly ought not to be, because they recognise that pain and death cannot lie in the eternal, original, and immutable order of things, in that which in every respect ought to be. The power by virtue of which Christianity was able to overcome first Judaism, and then the heathenism of Greece and Rome, lies solely in its pessimism, in the confession that our state is both exceedingly wretched and sinful, while Judaism and heathenism were optimistic. That truth, profoundly and painfully felt by all, penetrated, and bore in its train the need of redemption.

I turn to a general consideration of the other kind of metaphysics, that which has its authentication in itself, and is called *philosophy*. I remind the reader of its origin, mentioned above, in a *wonder* concerning the world and our own existence, inasmuch as these press upon the intellect as a riddle, the solution of which therefore occupies mankind without intermission. Here, then, I wish first of all to draw attention to the fact that this could not be the case if, in Spinoza's sense, which in our own day has so often been brought forward again under modern forms and expositions as pantheism, the world were an "*absolute substance*," and therefore an *absolutely necessary existence*. For this means that it exists with so great a necessity that beside it every other necessity comprehensible to our understanding as such must appear as an accident. It would then be something which comprehended in itself not only all actual but also all possible existence, so that, as Spinoza indeed declares, its possibility and its actuality would be absolutely one. Its non-being would therefore be impossibility itself; thus it would be something the non-being or other-being of which must be completely inconceivable, and which could therefore just as little be thought away as, for example, space or time. And since, further, *we*

ourselves would be parts, modes, attributes, or accidents of such an absolute substance, which would be the only thing that, in any sense, could ever or anywhere exist, our and its existence, together with its properties, would necessarily be very far from presenting itself to us as remarkable, problematical, and indeed as an unfathomable and ever-disquieting riddle, but, on the contrary, would be far more self-evident than that two and two make four. For we would necessarily be incapable of thinking anything else than that the world is, and is, as it is; and therefore we would necessarily be as little conscious of its existence *as such*, *i.e.*, as a problem for reflection, as we are of the incredibly fast motion of our planet.

All this, however, is absolutely not the case. Only to the brutes, who are without thought, does the world and existence appear as a matter of course; to man, on the contrary, it is a problem, of which even the most uneducated and narrow-minded becomes vividly conscious in certain brighter moments, but which enters more distinctly and more permanently into the consciousness of each one of us the clearer and more enlightened that consciousness is, and the more material for thought it has acquired through culture, which all ultimately rises, in minds that are naturally adapted for philosophising, to Plato's "θαυμαζειν, μαλα φιλοσοφικον παθος" (*mirari, valde philosophicus affectus*), that is, to that *wonder* which comprehends in its whole magnitude that problem which unceasingly occupies the nobler portion of mankind in every age and in every land, and gives it no rest. In fact, the pendulum which keeps in motion the clock of metaphysics, that never runs down, is the consciousness that the non-existence of this world is just as possible as its existence. Thus, then, the Spinozistic view of it as an absolutely necessary existence, that is, as something that absolutely and in every sense ought to and must be, is a false one. Even simple Theism, since in its cosmological proof it tacitly starts by inferring the previous non-existence of the world from its existence, thereby assumes beforehand that the world is something contingent. Nay, what is more, we very soon apprehend the world as something the non-existence of which is not only conceivable, but indeed preferable to its existence. Therefore our wonder at it easily passes into a brooding over the *fatality* which could yet call forth its existence, and by virtue of which such stupendous power as is demanded for the production and maintenance of such a world could be directed so much against its own interest. The philosophical astonishment is therefore at bottom perplexed and melancholy; philosophy, like the overture to "Don

Juan," commences with a minor chord. It follows from this that it can neither be Spinozism nor optimism. The more special nature, which has just been indicated, of the astonishment which leads us to philosophise clearly springs from the sight of the *suffering and the wickedness* in the world, which, even if they were in the most just proportion to each other, and also were far outweighed by good, are yet something which absolutely and in general ought not to be. But since now nothing can come out of nothing, these also must have their germ in the origin or in the kernel of the world itself. It is hard for us to assume this if we look at the magnitude, the order and completeness, of the physical world, for it seems to us that what had the power to produce such a world must have been able to avoid the suffering and the wickedness. That assumption (the truest expression of which is Ormuzd and Ahrimines), it is easy to conceive, is hardest of all for Theism. Therefore the freedom of the will was primarily invented to account for wickedness. But this is only a concealed way of making something out of nothing, for it assumes an *Operari* that proceeded from no *Esse* (see Die beiden *Grundprobleme der Ethik*, p. 58, *et seq.*; second edition, p. 57 *et seq.*.) Then it was sought to get rid of evil by attributing it to matter, or to unavoidable necessity, whereby the devil, who is really the right *Expediens ad hoc*, was unwillingly set aside. To evil also belongs *death*; but wickedness is only the throwing of the existing evil from oneself on to another. Thus, as was said above, it is wickedness, evil, and death that qualify and intensify the philosophical astonishment. Not merely that the world exists, but still more that it is such a wretched world, is the *punctum pruriens* of metaphysics, the problem which awakens in mankind an unrest that cannot be quieted by scepticism nor yet by criticism.

We find *physics* also (in the widest sense of the word) occupied with the explanation of the phenomena in the world. But it lies in the very nature of its explanations themselves that they cannot be sufficient. Physics cannot stand on its own feet, but requires a metaphysic to lean upon, whatever airs it may give itself towards the latter. For it explains the phenomena by something still more unknown than they are themselves; by laws of nature, resting upon forces of nature, to which the power of life also belongs. Certainly the whole present condition of all things in the world, or in nature, must necessarily be explicable from purely physical causes. But such an explanation — supposing one actually succeeded so far as to be able to give it — must always just as necessarily be tainted with two imperfections

(as it were with two sores, or like Achilles with the vulnerable heel, or the devil with the horse's hoof), on account of which everything so explained really remains still unexplained. First with this imperfection, that the *beginning* of every explanatory chain of causes and effects, *i.e.*, of connected changes, can absolutely *never* be reached, but, just like the limits of the world in space and time, unceasingly recedes *in infinito*. Secondly with this, that the whole of the efficient causes out of which everything is explained constantly rest upon something which is completely inexplicable, the original *qualities* of things and the *natural forces* which play a prominent part among them, by virtue of which they produce a specific kind of effect, *e.g.*, weight, hardness, impulsive force, elasticity, warmth, electricity, chemical forces, &c., and which now remain in every explanation which is given, like an unknown quantity, which absolutely cannot be eliminated, in an otherwise perfectly solved algebraical equation. Accordingly there is no fragment of clay, however little worth, that is not entirely composed of inexplicable qualities. Thus these two inevitable defects in every purely physical, *i.e.*, causal, explanation show that such an explanation can only be *relative*, and that its whole method and nature cannot be the only one, the ultimate and thus the sufficient one, *i.e.*, cannot be the method of explanation that can ever lead to the satisfactory solution of the difficult riddle of things, and to the true understanding of the world and existence; but that the physical explanation in general and as such requires further a *metaphysical* explanation, which affords us the key to all its assumptions, but just on this account must necessarily follow quite a different path. The first step to this is that one should bring to distinct consciousness and firmly retain the difference of the two, hence the difference between *physics* and *metaphysics*. It rests in general on the Kantian distinction between *phenomenon* and *thing in itself*. Just because Kant held the latter to be absolutely unknowable, there was, according to him, no *metaphysics*, but merely immanent knowledge, *i.e.*, *physics*, which throughout can speak only of phenomena, and also a critique of the reason which strives after metaphysics. Here, however, in order to show the true point of connection between my philosophy and that of Kant, I shall anticipate the second book, and give prominence to the fact that Kant, in his beautiful exposition of the compatibility of freedom and necessity (Critique of Pure Reason, first edition, p. 532-554; and Critique of Practical Reason, p. 224-231 of Rosenkranz's edition), shows how one and the same action

may in one aspect be perfectly explicable as necessarily arising from the character of the man, the influence to which he has been subject in the course of his life, and the motives which are now present to him, but yet in another aspect must be regarded as the work of his free will; and in the same sense he says, § 53 of the "Prolegomena:" "Certainly natural necessity will belong to every connection of cause and effect in the world of sense; yet, on the other hand, freedom will be conceded to that cause which is not itself a phenomenon (though indeed it is the ground of phenomena), thus nature and freedom may without contradiction be attributed to the same thing, but in a different reference — in the one case as a phenomenon, in the other case as a thing in itself." What, then, Kant teaches of the phenomenon of man and his action my teaching extends to *all* phenomena in nature, in that it makes the *will* as a thing in itself their foundation. This proceeding is justified first of all by the fact that it must not be assumed that man is specifically *toto genere* radically different from the other beings and things in nature, but rather that he is different only in degree. I turn back from this premature digression to our consideration of the inadequacy of physics to afford us the ultimate explanation of things. I say, then, everything certainly is physical, but yet nothing is explicable physically. As for the motion of the projected bullet, so also for the thinking of the brain, a physical explanation must ultimately be in itself possible, which would make the latter just as comprehensible as is the former. But even the former, which we imagine we understand so perfectly, is at bottom as obscure to us as the latter; for what the inner nature of expansion in space may be — of impenetrability, mobility, hardness, elasticity, and gravity remains, after all physical explanations, a mystery, just as much as thought. But because in the case of thought the inexplicable appears most immediately, a spring was at once made here from physics to metaphysics, and a substance of quite a different kind from all corporeal substances was hypostatised — a soul was set up in the brain. But if one had not been so dull as only to be capable of being struck by the most remarkable of phenomena, one would have had to explain digestion by a soul in the stomach, vegetation by a soul in the plant, affinity by a soul in the reagents, nay, the falling of a stone by a soul in the stone. For the quality of every unorganised body is just as mysterious as the life in the living body. In the same way, therefore, the physical explanation strikes everywhere upon what is metaphysical, by which it is annihilated, *i.e.*, it ceases to be explanation. Strictly speaking, it may be asserted that no

natural science really achieves anything more than what is also achieved by Botany: the bringing together of similars, classification. A physical system which asserted that its explanations of things — in the particular from causes, and in general from forces — were really sufficient, and thus exhausted the nature of the world, would be the true *Naturalism*. From Leucippus, Democritus, and Epicurus down to the *Système de la Nature*, and further, to Delamark, Cabanis, and to the materialism that has again been warmed up in the last few years, we can trace the persistent attempt to set up a *system of physics without metaphysics*, that is, a system which would make the phenomenon the thing in itself. But all their explanations seek to conceal from the explainers themselves and from others that they simply assume the principal matter without more ado. They endeavour to show that all phenomena, even those of mind, are physical. And they are right; only they do not see that all that is physical is in another aspect also metaphysical. But, without Kant, this is indeed difficult to see, for it presupposes the distinction of the phenomenon from the thing in itself. Yet without this Aristotle, much as he was inclined to empiricism, and far as he was removed from the Platonic hyper-physics, kept himself free from this limited point of view. He says: "Ει μεν ουν μη εστι τις ἑτερα ουσια παρα τας φυσει συνεστηκυιας, ἡ φυσικη αν ειη πρωτη επιστημη; ει δε εστι τις ουσια ακινητος, αὑτη προτερα και φιλοσοφια πρωτη, και καθολου οὑτως, ὁτι πρωτη; και περι του οντοσ ᾑ ον, ταυτης αν ειη θεωρησαι." (*Si igitur non est aliqua alia substantia, prœter eas, quœ natura consistunt, physica profecto prima scientia esset: quodsi autem est aliqua substantia immobilis, hœc prior et philosophia prima, et universalis sic, quod prima; et de ente, prout ens est, speculari hujus est*), "Metaph.," v. 1. Such an *absolute system of physics* as is described above, which leaves room for no *metaphysics*, would make the *Natura naturata* into the *Natura naturans*; it would be physics established on the throne of metaphysics, yet it would comport itself in this high position almost like Holberg's theatrical would-be politician who was made burgomaster. Indeed behind the reproach of atheism, in itself absurd, and for the most part malicious, there lies, as its inner meaning and truth, which gives it strength, the obscure conception of such an absolute system of physics without metaphysics. Certainly such a system would necessarily be destructive of ethics; and while Theism has falsely been held to be inseparable from morality, this is really true only of

metaphysics in general, *i.e.*, of the knowledge that the order of nature is not the only and absolute order of things. Therefore we may set up this as the necessary *Credo* of all just and good men: "I believe in metaphysics." In this respect it is important and necessary that one should convince oneself of the untenable nature of an *absolute system of physics*, all the more as this, the true *naturalism*, is a point of view which of its own accord and ever anew presses itself upon a man, and can only be done away with through profound speculation. In this respect, however, all kinds of systems and faiths, so far and so long as they are accepted, certainly serve as a substitute for such speculation. But that a fundamentally false view presses itself upon man of its own accord, and must first be skilfully removed, is explicable from the fact that the intellect is not originally intended to instruct us concerning the nature of things, but only to show us their relations, with reference to our will; it is, as we shall find in the second book, only the medium of motives. Now, that the world schematises itself in the intellect in a manner which exhibits quite a different order of things from the absolutely true one, because it shows us, not their kernel, but only their outer shell, happens accidentally, and cannot be used as a reproach to the intellect; all the less as it nevertheless finds in itself the means of rectifying this error, in that it arrives at the distinction between the phenomenal appearance and the inner being of things, which distinction existed in substance at all times, only for the most part was very imperfectly brought to consciousness, and therefore was inadequately expressed, indeed often appeared in strange clothing. The Christian mystics, when they call it the *light of nature*, declare the intellect to be inadequate to the comprehension of the true nature of things. It is, as it were, a mere surface force, like electricity, and does not penetrate to the inner being.

The insufficiency of pure naturalism appears, as we have said, first of all, on the empirical path itself, through the circumstance that every physical explanation explains the particular from its cause; but the chain of these causes, as we know *a priori*, and therefore with perfect certainty, runs back to infinity, so that absolutely no cause could ever be the first. Then, however, the effect of every cause is referred to a law of nature, and this finally to a force of nature, which now remains as the absolutely inexplicable. But this inexplicable, to which all phenomena of this so clearly given and naturally explicable world, from the highest to the lowest, are referred, just shows that the whole nature of such explanation is only

conditional, as it were only *ex concessis*, and by no means the true and sufficient one; therefore I said above that physically everything and nothing is explicable. That absolutely inexplicable element which pervades all phenomena, which is most striking in the highest, *e.g.*, in generation, but yet is just as truly present in the lowest, *e.g.*, in mechanical phenomena, points to an entirely different kind of order of things lying at the foundation of the physical order, which is just what Kant calls the order of things in themselves, and which is the goal of metaphysics. But, secondly, the insufficiency of pure naturalism comes out clearly from that fundamental philosophical truth, which we have fully considered in the first half of this book, and which is also the theme of the "Critique of Pure Reason;" the truth that every *object*, both as regards its objective existence in general and as regards the manner (forms) of this existence, is throughout conditioned by the knowing *subject*, hence is merely a phenomenon, not a thing in itself. This is explained in § 7 of the first volume, and it is there shown that nothing can be more clumsy than that, after the manner of all materialists, one should blindly take the objective as simply given in order to derive everything from it without paying any regard to the subjective, through which, however, nay, in which alone the former exists. Samples of this procedure are most readily afforded us by the fashionable materialism of our own day, which has thereby become a philosophy well suited for barbers' and apothecaries' apprentices. For it, in its innocence, matter, assumed without reflection as absolutely real, is the thing in self, and the one capacity of a thing in itself is impulsive force, for all other qualities can only be manifestations of this.

With naturalism, then, or the purely physical way of looking at things, we shall never attain our end; it is like a sum that never comes out. Causal series without beginning or end, fundamental forces which are inscrutable, endless space, beginningless time, infinite divisibility of matter, and all this further conditioned by a knowing brain, in which alone it exists just like a dream, and without which it vanishes — constitute the labyrinth in which naturalism leads us ceaselessly round. The height to which in our time the natural sciences have risen in this respect entirely throws into the shade all previous centuries, and is a summit which mankind reaches for the first time. But however great are the advances which *physics* (understood in the wide sense of the ancients) may make, not the smallest step towards *metaphysics* is thereby taken, just as a plane can never obtain cubical

content by being indefinitely extended. For all such advances will only perfect our knowledge of the *phenomenon*; while *metaphysics* strives to pass beyond the phenomenal appearance itself, to that which so appears. And if indeed it had the assistance of an entire and complete experience, it would, as regards the main point, be in no way advantaged by it. Nay, even if one wandered through all the planets and fixed stars, one would thereby have made no step in *metaphysics*. It is rather the case that the greatest advances of physics will make the need of metaphysics ever more felt; for it is just the corrected, extended, and more thorough knowledge of nature which, on the one hand, always undermines and ultimately overthrows the metaphysical assumptions which till then have prevailed, but, on the other hand, presents the problem of metaphysics itself more distinctly, more correctly, and more fully, and separates it more clearly from all that is merely physical; moreover, the more perfectly and accurately known nature of the particular thing more pressingly demands the explanation of the whole and the general, which, the more correctly, thoroughly, and completely it is known empirically, only presents itself as the more mysterious. Certainly the individual, simple investigator of nature, in a special branch of physics, does not at once become clearly conscious of all this; he rather sleeps contentedly by the side of his chosen maid, in the house of Odysseus, banishing all thoughts of Penelope (cf. ch. 12 at the end). Hence we see at the present day the *husk of nature* investigated in its minutest details, the intestines of intestinal worms and the vermin of vermin known to a nicety. But if some one comes, as, for example, I do, and speaks of the *kernel of nature*, they will not listen; they even think it has nothing to do with the matter, and go on sifting their husks. One finds oneself tempted to call that over-microscopical and micrological investigator of nature the cotquean of nature. But those persons who believe that crucibles and retorts are the true and only source of all wisdom are in their own way just as perverse as were formerly their antipodes the Scholastics. As the latter, absolutely confined to their abstract conceptions, used these as their weapons, neither knowing nor investigating anything outside them, so the former, absolutely confined to their empiricism, allow nothing to be true except what their eyes behold, and believe they can thus arrive at the ultimate ground of things, not discerning that between the phenomenon and that which manifests itself in it, the thing in itself, there is a deep gulf, a radical difference, which can only be cleared up by the knowledge and

accurate delimitation of the subjective element of the phenomenon, and the insight that the ultimate and most important conclusions concerning the nature of things can only be drawn from self-consciousness; yet without all this one cannot advance a step beyond what is directly given to the senses, thus can get no further than to the problem. Yet, on the other hand, it is to be observed that the most perfect possible knowledge of nature is the corrected *statement of the problem* of metaphysics. Therefore no one ought to venture upon this without having first acquired a knowledge of all the branches of natural science, which, though general, shall be thorough, clear, and connected. For the problem must precede its solution. Then, however, the investigator must turn his glance inward; for the intellectual and ethical phenomena are more important than the physical, in the same proportion as, for example, animal magnetism is a far more important phenomenon than mineral magnetism. The last fundamental secret man carries within himself, and this is accessible to him in the most immediate manner; therefore it is only here that he can hope to find the key to the riddle of the world and gain a clue to the nature of all things. The special province of metaphysics thus certainly lies in what has been called mental philosophy.

"The ranks of living creatures thou dost lead
Before me, teaching me to know my brothers
In air and water and the silent wood:
Then to the cave secure thou leadest me,
Then show'st me mine own self, and in my breast
The deep, mysterious miracles unfold."[28]

Finally, then, as regards the *source or the foundation* of metaphysical knowledge, I have already declared myself above to be opposed to the assumption, which is even repeated by Kant, that it must lie *in mere conceptions*. In no knowledge can conceptions be what is first; for they are always derived from some perception. What has led, however, to that assumption is probably the example of mathematics. Mathematics can leave perception altogether, and, as is especially the case in algebra, trigonometry, and analysis, can operate with purely abstract conceptions, nay, with conceptions which are represented only by signs instead of words, and can yet arrive at a perfectly certain result, which is still so remote that any one who adhered to the firm ground of perception could not arrive at it. But the possibility of this depends, as Kant has clearly shown, on the fact that the conceptions of mathematics are derived from the most certain and definite

of all perceptions, from the *a priori* and yet intuitively known relations of quantity, and can therefore be constantly realised again and controlled by these, either arithmetically, by performing the calculations which are merely indicated by those signs, or geometrically, by means of what Kant calls the construction of the conceptions. This advantage, on the other hand, is not possessed by the conceptions out of which it was believed metaphysics could be built up; such, for example, as essence, being, substance, perfection, necessity, reality, finite, infinite, absolute, ground, &c. For such conceptions are by no means original, as fallen from heaven, or innate; but they also, like all conceptions, are derived from perceptions; and as, unlike the conceptions of mathematics, they do not contain the mere form of perception, but more, empirical perceptions must lie at their foundation. Thus nothing can be drawn from them which the empirical perceptions did not also contain, that is, nothing which was not a matter of experience, and which, since these conceptions are very wide abstractions, we would receive with much greater certainty at first hand from experience. For from conceptions nothing more can ever be drawn than the perceptions from which they are derived contain. If we desire pure conceptions, *i.e.*, such as have no empirical source, the only ones that can be produced are those which concern space and time, *i.e.*, the merely formal part of perception, consequently only the mathematical conceptions, or at most also the conception of causality, which indeed does not originate in experience, but yet only comes into consciousness by means of it (first in sense-perception); therefore experience indeed is only possible by means of it; but it also is only valid in the sphere of experience, on which account Kant has shown that it only serves to communicate the connection of experience, and not to transcend it; that thus it admits only of physical application, not of metaphysical. Certainly only its *a priori* origin can give apodictic certainty to any knowledge; but this limits it to the mere *form* of experience in general, for it shows that it is conditioned by the subjective nature of the intellect. Such knowledge, then, far from taking us beyond experience, gives only one *part* of experience itself, the *formal* part, which belongs to it throughout, and therefore is universal, consequently mere form without content. Since now metaphysics can least of all be confined to this, it must have also *empirical* sources of knowledge; therefore that preconceived idea of a metaphysic to be found purely *a priori* is necessarily vain. It is really a *petitio principii* of Kant's, which he expresses most distinctly in § 1 of the

Prolegomena, that metaphysics must not draw its fundamental conceptions and principles from experience. In this it is assumed beforehand that only what we knew *before* all experience can extend beyond all possible experience. Supported by this, Kant then comes and shows that all such knowledge is nothing more than the form of the intellect for the purpose of experience, and consequently can never lead beyond experience, from which he then rightly deduces the impossibility of all metaphysics. But does it not rather seem utterly perverse that in order to discover the secret of experience, *i.e.*, of the world which alone lies before us, we should look quite away from it, ignore its content, and take and use for its material only the empty forms of which we are conscious *a priori*? Is it not rather in keeping with the matter that *the science of experience in general*, and as such, should also be drawn from experience? Its problem itself is given it empirically; why should not the solution of it call in the assistance of experience? Is it not senseless that he who speaks of the nature of things should not look at things themselves, but should confine himself to certain abstract conceptions? The task of metaphysics is certainly not the observation of particular experiences, but yet it is the correct explanation of experience as a whole. Its foundation must therefore, at any rate, be of an empirical nature. Indeed the *a priori* nature of a part of human knowledge will be apprehended by it as a given *fact*, from which it will infer the subjective origin of the same. Only because the consciousness of its *a priori* nature accompanies it is it called by Kant *transcendental* as distinguished from *transcendent*, which signifies "passing beyond all possibility of experience," and has its opposite in *immanent*, *i.e.*, remaining within the limits of experience. I gladly recall the original meaning of this expression introduced by Kant, with which, as also with that of the Categories, and many others, the apes of philosophy carry on their game at the present day. Now, besides this, the source of the knowledge of metaphysics is not *outer* experience alone, but also *inner*. Indeed, what is most peculiar to it, that by which the decisive step which alone can solve the great question becomes possible for it, consists, as I have fully and thoroughly proved in "*Ueber den Willen in der Natur*," under the heading, "*Physische Astronomie*," in this, that at the right place it combines outer experience with inner, and uses the latter as a key to the former.

The origin of metaphysics in empirical sources of knowledge, which is here set forth, and which cannot fairly be denied, deprives it certainly of that kind of apodictic certainty which is only possible through knowledge *a priori*. This remains the possession of logic and mathematics — sciences, however, which really only teach what every one knows already, though not distinctly. At most the primary elements of natural science may also be deduced from knowledge *a priori*. By this confession metaphysics only surrenders an ancient claim, which, according to what has been said above, rested upon misunderstanding, and against which the great diversity and changeableness of metaphysical systems, and also the constantly accompanying scepticism, in every age has testified. Yet against the possibility of metaphysics in general this changeableness cannot be urged, for the same thing affects just as much all branches of natural science, chemistry, physics, geology, zoology, &c., and even history has not remained exempt from it. But when once, as far as the limits of human intellect allow, a true system of metaphysics shall have been found, the unchangeableness of a science which is known *a priori* will yet belong to it; for its foundation can only be *experience in general*, and not the particular and special experiences by which, on the other hand, the natural sciences are constantly modified and new material is always being provided for history. For experience as a whole and in general will never change its character for a new one.

The next question is: How can a science drawn from experience pass beyond it and so merit the name of metaphysics? It cannot do so perhaps in the same way as we find a fourth number from three proportionate ones, or a triangle from two sides and an angle. This was the way of the pre-Kantian dogmatism, which, according to certain laws known to us *a priori*, sought to reason from the given to the not given, from the consequent to the reason, thus from experience to that which could not possibly be given in any experience. Kant proved the impossibility of a metaphysic upon this path, in that he showed that although these laws were not drawn from experience, they were only valid for experience. He therefore rightly taught that in such a way we cannot transcend the possibility of all experience. But there are other paths to metaphysics. The whole of experience is like a cryptograph, and philosophy the deciphering of it, the correctness of which is proved by the connection appearing everywhere. If this whole is only profoundly enough comprehended, and the inner experience is connected with the

outer, it must be capable of being *interpreted*, *explained* from itself. Since Kant has irrefutably proved to us that experience in general proceeds from two elements, the forms of knowledge and the inner nature of things, and that these two may be distinguished in experience from each other, as that of which we are conscious *a priori* and that which is added *a posteriori*, it is possible, at least in general, to say, what in the given experience, which is primarily merely phenomenal, belongs to the *form* of this phenomenon, conditioned by the intellect, and what, after deducting this, remains over for the *thing in itself*. And although no one can discern the thing in itself through the veil of the forms of perception, on the other hand every one carries it in himself, indeed is it himself; therefore in self-consciousness it must be in some way accessible to him, even though only conditionally. Thus the bridge by which metaphysics passes beyond experience is nothing else than that analysis of experience into phenomenon and thing in itself in which I have placed Kant's greatest merit. For it contains the proof of a kernel of the phenomenon different from the phenomenon itself. This can indeed never be entirely separated from the phenomenon and regarded in itself as an *ens extramundanum*, but is always known only in its relations to and connections with the phenomenon itself. But the interpretation and explanation of the latter, in relation to the former, which is its inner kernel, is capable of affording us information with regard to it which does not otherwise come into consciousness. In this sense, then, metaphysics goes beyond the phenomenon, *i.e.*, nature, to that which is concealed in or behind it (το μετα το φυσικον), always regarding it, however, merely as that which manifests itself in the phenomenon, not as independent of all phenomenal appearance; it therefore remains immanent, and does not become transcendent. For it never disengages itself entirely from experience, but remains merely its interpretation and explanation, since it never speaks of the thing in itself otherwise than in its relation to the phenomenon. This at least is the sense in which I, with reference throughout to the limitations of human knowledge proved by Kant, have attempted to solve the problem of metaphysics. Therefore his Prolegomena to future metaphysics will be valid and suitable for mine also. Accordingly it never really goes beyond experience, but only discloses the true understanding of the world which lies before it in experience. It is neither, according to the definition of metaphysics which even Kant repeats, a science of mere conceptions, nor is it a system of deductions from *a priori* principles, the uselessness of which

for the *end* of metaphysics has been shown by Kant. But it is rational knowledge, drawn from perception of the external actual world and the information which the most intimate fact of self-consciousness affords us concerning it, deposited in distinct conceptions. It is accordingly the science of experience; but its subject and its source is not particular experiences, but the totality of all experience. I completely accept Kant's doctrine that the world of experience is merely phenomenal, and that the *a priori* knowledge is valid only in relation to phenomena; but I add that just as phenomenal appearance, it is the manifestation of that which appears, and with him I call this the thing in itself. This must therefore express its nature and character in the world of experience, and consequently it must be possible to interpret these from this world, and indeed from the matter, not the mere form, of experience. Accordingly philosophy is nothing but the correct and universal understanding of experience itself, the true exposition of its meaning and content. To this the metaphysical, *i.e.*, that which is merely clothed in the phenomenon and veiled in its forms, is that which is related to it as thought to words.

Such a deciphering of the world with reference to that which manifests itself in it must receive its confirmation from itself, through the agreement with each other in which it places the very diverse phenomena of the world, and which without it we do not perceive. If we find a document the alphabet of which is unknown, we endeavour to make it out until we hit upon an hypothesis as to the significance of the letters in accordance with which they make up comprehensible words and connected sentences. Then, however, there remains no doubt as to the correctness of the deciphering, because it is not possible that the agreement and connection in which all the letters of that writing are placed by this explanation is merely accidental, and that by attributing quite a different value to the letters we could also recognise words and sentences in this arrangement of them. In the same way the deciphering of the world must completely prove itself from itself. It must throw equal light upon all the phenomena of the world, and also bring the most heterogeneous into agreement, so that the contradiction between those which are most in contrast may be abolished. This proof from itself is the mark of genuineness. For every false deciphering, even if it is suitable for some phenomena, will conflict all the more glaringly with the rest. So, for example, the optimism of Leibnitz conflicts with the palpable misery of existence; the doctrine of Spinoza, that the world is the only possible and

absolutely necessary substance, is incompatible with our wonder at its existence and nature; the Wolfian doctrine, that man obtains his *Existentia* and *Essentia* from a will foreign to himself, is contradicted by our moral responsibility for the actions which proceed with strict necessity from these, in conflict with the motives; the oft-repeated doctrine of the progressive development of man to an ever higher perfection, or in general of any kind of becoming by means of the process of the world, is opposed to the *a priori* knowledge that at any point of time an infinite time has already run its course, and consequently all that is supposed to come with time would necessarily have already existed; and in this way an interminable list might be given of the contradictions of dogmatic assumptions with the given reality of things. On the other hand, I must deny that any doctrine of my philosophy could fairly be added to such a list, because each of them has been thought out in the presence of the perceived reality, and none of them has its root in abstract conceptions alone. There is yet in it a fundamental thought which is applied to all the phenomena of the world as their key; but it proves itself to be the right alphabet at the application of which all words and sentences have sense and significance. The discovered answer to a riddle shows itself to be the right one by the fact that all that is said in the riddle is suitable to it. In the same way my doctrine introduces agreement and connection into the confusion of the contrasting phenomena of this world, and solves the innumerable contradictions which, when regarded from any other point of view, it presents. Therefore, so far, it is like a sum that comes out right, yet by no means in the sense that it leaves no problem over to solve, no possible question unanswered. To assert anything of that sort would be a presumptuous denial of the limits of human knowledge in general. Whatever torch we may kindle, and whatever space it may light, our horizon will always remain bounded by profound night. For the ultimate solution of the riddle of the world must necessarily be concerned with the things in themselves, no longer with the phenomena. But all our forms of knowledge are adapted to the phenomena alone; therefore we must comprehend everything through coexistence, succession, and causal relations. These forms, however, have meaning and significance only with reference to the phenomenon; the things in themselves and their possible relations cannot be apprehended by means of those forms. Therefore the actual, positive solution of the riddle of the world must be something that human intellect is absolutely incapable of grasping and thinking; so that if a

being of a higher kind were to come and take all pains to impart it to us, we would be absolutely incapable of understanding anything of his expositions. Those, therefore, who profess to know the ultimate, *i.e.*, the first ground of things, thus a primordial being, an absolute, or whatever else they choose to call it, together with the process, the reasons, motives, or whatever it may be, in consequence of which the world arises from it, or springs, or falls, or is produced, set in existence, "discharged," and ushered forth, are playing tricks, are vain boasters, when indeed they are not charlatans.

I regard it as a great excellence of my philosophy that all its truths have been found independently of each other, by contemplation of the real world; but their unity and agreement, about which I had been unconcerned, has always afterwards appeared of itself. Hence also it is rich, and has wide-spreading roots in the ground of perceptible reality, from which all nourishment of abstract truths springs; and hence, again, it is not wearisome — a quality which, to judge from the philosophical writings of the last fifty years, one might regard as essential to philosophy. If, on the other hand, all the doctrines of a philosophy are merely deduced the one out of the other, and ultimately indeed all out of one first principle, it must be poor and meagre, and consequently wearisome, for nothing can follow from a proposition except what it really already says itself. Moreover, in this case everything depends upon the correctness of *one* proposition, and by a single mistake in the deduction the truth of the whole would be endangered. Still less security is given by the systems which start from an intellectual intuition, *i.e.*, a kind of ecstasy or clairvoyance. All knowledge so obtained must be rejected as subjective, individual, and consequently problematical. Even if it actually existed it would not be communicable, for only the normal knowledge of the brain is communicable; if it is abstract, through conceptions and words; if purely perceptible or concrete, through works of art.

If, as so often happens, metaphysics is reproached with having made so little progress, it ought also to be considered that no other science has grown up like it under constant oppression, none has been so hampered and hindered from without as it has always been by the religion of every land, which, everywhere in possession of a monopoly of metaphysical knowledge, regards metaphysics as a weed growing beside it, as an unlicensed worker, as a horde of gipsies, and as a rule tolerates it only under the condition that it accommodates itself to serve and follow it. For where

has there ever been true freedom of thought? It has been vaunted sufficiently; but whenever it wishes to go further than perhaps to differ about the subordinate dogmas of the religion of the country, a holy shudder seizes the prophets of tolerance, and they say: “Not a step further!” What progress of metaphysics was possible under such oppression? Nay, this constraint which the privileged metaphysics exercises is not confined to the *communication* of thoughts, but extends to *thinking* itself, for its dogmas are so firmly imprinted in the tender, plastic, trustful, and thoughtless age of childhood, with studied solemnity and serious airs, that from that time forward they grow with the brain, and almost assume the nature of innate thoughts, which some philosophers have therefore really held them to be, and still more have pretended to do so. Yet nothing can so firmly resist the comprehension of even the *problem* of metaphysics as a previous solution of it intruded upon and early implanted in the mind. For the necessary starting-point for all genuine philosophy is the deep feeling of the Socratic: “This one thing I know, that I know nothing.” The ancients were in this respect in a better position than we are, for their national religions certainly limited somewhat the imparting of thoughts; but they did not interfere with the freedom of thought itself, because they were not formally and solemnly impressed upon children, and in general were not taken so seriously. Therefore in metaphysics the ancients are still our teachers.

Whenever metaphysics is reproached with its small progress, and with not having yet reached its goal in spite of such sustained efforts, one ought further to consider that in the meanwhile it has constantly performed the invaluable service of limiting the boundless claims of the privileged metaphysics, and yet at the same time combating naturalism and materialism proper, which are called forth by it as an inevitable reaction. Consider to what a pitch the arrogance of the priesthood of every religion would rise if the belief in their doctrines was as firm and blind as they really wish. Look back also at the wars, disturbances, rebellions, and revolutions in Europe from the eighth to the eighteenth century; how few will be found that have not had as their essence, or their pretext, some controversy about beliefs, thus a metaphysical problem, which became the occasion of exciting nations against each other. Yet is that whole thousand years a continual slaughter, now on the battlefield, now on the scaffold, now in the streets, in metaphysical interests! I wish I had an authentic list of all crimes which Christianity has really prevented, and all good deeds it has really

performed, that I might be able to place them in the other scale of the balance.

Lastly, as regards the *obligations* of metaphysics, it has only one; for it is one which endures no other beside it — the obligation to be *true*. If one would impose other obligations upon it besides this, such as to be spiritualistic, optimistic, monotheistic, or even only to be moral, one cannot know beforehand whether this would not interfere with the fulfilment of that first obligation, without which all its other achievements must clearly be worthless. A given philosophy has accordingly no other standard of its value than that of truth. For the rest, philosophy is essentially *world-wisdom*: its problem is the world. It has to do with this alone, and leaves the gods in peace — expects, however, in return, to be left in peace by them.

Supplements to the Second Book.

“Ihr folget falscher Spur,
Denkt nicht, wir scherzen!
Ist nicht der Kern der Natur
Menschen im Herzen?”
— Goethe.

Chapter XVIII.[29] On The Possibility Of Knowing The Thing In Itself.

In 1836 I already published, under the title "*Ueber den Willen in der Natur*" (second ed., 1854; third ed., 1867), the most essential supplement to this book, which contains the most peculiar and important step in my philosophy, the transition from the phenomenon to the thing in itself, which Kant gave up as impossible. It would be a great mistake to regard the foreign conclusions with which I have there connected my expositions as the real material and subject of that work, which, though small as regards its extent, is of weighty import. These conclusions are rather the mere occasion starting from which I have there expounded that fundamental truth of my philosophy with so much greater clearness than anywhere else, and brought it down to the empirical knowledge of nature. And indeed this is done most exhaustively and stringently under the heading "*Physische Astronomie*;" so that I dare not hope ever to find a more correct or accurate expression of that core of my philosophy than is given there. Whoever desires to know my philosophy thoroughly and to test it seriously must therefore give attention before everything to that section. Thus, in general, all that is said in that little work would form the chief content of these supplements, if it had not to be excluded on account of having preceded them; but, on the other hand, I here take for granted that it is known, for otherwise the very best would be wanting.

I wish now first of all to make a few preliminary observations from a general point of view as to the sense in which we can speak of a knowledge of the thing in itself and of its necessary limitation.

What is *knowledge*? It is primarily and essentially *idea*. What is *idea*? A very complicated *physiological* process in the brain of an animal, the result of which is the consciousness of a *picture* there. Clearly the relation between such a picture and something entirely different from the animal in whose brain it exists can only be a very indirect one. This is perhaps the simplest and most comprehensible way of disclosing the *deep gulf between the ideal and the real*. This belongs to the things of which, like the motion of the earth, we are not directly conscious; therefore the ancients did not observe it, just as they did not observe the motion of the earth. Once pointed out, on the other hand, first by Descartes, it has ever since given

philosophers no rest. But after Kant had at last proved in the most thorough manner the complete diversity of the ideal and the real, it was an attempt, as bold as it was absurd, yet perfectly correctly calculated with reference to the philosophical public in Germany, and consequently crowned with brilliant results, to try to assert the *absolute identity* of the two by dogmatic utterances, on the strength of a pretended intellectual intuition. In truth, on the contrary, a subjective and an objective existence, a being for self and a being for others, a consciousness of one's own self, and a consciousness of other things, is given us directly, and the two are given in such a fundamentally different manner that no other difference can compare with this. About himself every one knows directly, about all others only very indirectly. This is the fact and the problem.

Whether, on the other hand, through further processes in the interior of a brain, general conceptions (*Universalia*) are abstracted from the perceptible ideas or images that have arisen within it, for the assistance of further combinations, whereby knowledge becomes *rational*, and is now called *thinking* — this is here no longer the essential question, but is of subordinate significance. For all such *conceptions* receive their content only from the perceptible idea, which is therefore *primary knowledge*, and has consequently alone to be taken account of in an investigation of the relation between the ideal and the real. It therefore shows entire ignorance of the problem, or at least it is very inept, to wish to define that relation as that between *being* and *thinking*. Thinking has primarily only a relation to *perceiving*, but *perception* has a relation to the *real being* of what is perceived, and this last is the great problem with which we are here concerned. Empirical being, on the other hand, as it lies before us, is nothing else than simply being given in perception; but the relation of the latter to *thinking* is no riddle, for the conceptions, thus the immediate materials of thought, are obviously *abstracted* from perception, which no reasonable man can doubt. It may be said in passing that one can see how important the choice of expressions in philosophy is from the fact that that inept expression condemned above, and the misunderstanding which arose from it, became the foundation of the whole Hegelian pseudo-philosophy, which has occupied the German public for twenty-five years.

If, however, it should be said: "The perception is itself the knowledge of the thing in itself: for it is the effect of that which is outside of us, and as this *acts*, so it *is*: its action is just its being;" to this we reply: (1.) that the

law of causality, as has been sufficiently proved, is of subjective origin, as well as the sensation from which the perception arises; (2.) that at any rate time and space, in which the object presents itself, are of subjective origin; (3.) that if the being of the object consists simply in its action, this means that it consists merely in the changes which it brings about in others; therefore itself and in itself it is nothing at all. Only of *matter* is it true, as I have said in the text, and worked out in the essay on the principle of sufficient reason, at the end of § 21, that its being consists in its action, that it is through and through only causality, thus is itself causality objectively regarded; hence, however, it is also nothing in itself (ἡ ὑλη το αληθινον ψευδος, *materia mendacium verax*), but as an ingredient in the perceived object, is a mere abstraction, which for itself alone can be given in no experience. It will be fully considered later on in a chapter of its own. But the perceived object must be something *in itself*, and not merely something *for others*. For otherwise it would be altogether merely idea, and we would have an absolute idealism, which would ultimately become theoretical egoism, with which all reality disappears and the world becomes a mere subjective phantasm. If, however, without further question, we stop altogether at the *world as idea*, then certainly it is all one whether I explain objects as ideas in my head or as phenomena exhibiting themselves in time and space; for time and space themselves exist only in my head. In this sense, then, an identity of the ideal and the real might always be affirmed; only, after Kant, this would not be saying anything new. Besides this, however, the nature of things and of the phenomenal world would clearly not be thereby exhausted; but with it we would always remain still upon the ideal side. The *real* side must be something *toto genere* different from *the world as idea*, it must be that which things are *in themselves*; and it is this entire diversity between the ideal and the real which Kant has proved in the most thorough manner.

Locke had denied to the senses the knowledge of things as they are in themselves; but Kant denied this also to the perceiving *understanding*, under which name I here comprehend what he calls the *pure* sensibility, and, as it is given *a priori*, the law of causality which brings about the empirical perception. Not only are both right, but we can also see quite directly that a contradiction lies in the assertion that a thing is known as it is in and for itself, *i.e.*, outside of knowledge. For all knowing is, as we have said, essentially a perceiving of ideas; but my perception of ideas, just

because it is mine, can never be identical with the inner nature of the thing outside of me. The being in and for itself, of everything, must necessarily be *subjective*; in the idea of another, however, it exists just as necessarily as *objective* — a difference which can never be fully reconciled. For by it the whole nature of its existence is fundamentally changed; as objective it presupposes a foreign subject, as whose idea it exists, and, moreover, as Kant has shown, has entered forms which are foreign to its own nature, just because they belong to that foreign subject, whose knowledge is only possible by means of them. If I, absorbed in this reflection, perceive, let us say lifeless bodies, of easily surveyed magnitude and regular, comprehensible form, and now attempt to conceive this spatial existence, in its three dimensions, as their being in itself, consequently as the existence which to the things is subjective, the impossibility of the thing is at once apparent to me, for I can never think those objective forms as the being which to the things is subjective, rather I become directly conscious that what I there perceive is only a picture produced in my brain, and existing only for me as the knowing subject, which cannot constitute the ultimate, and therefore subjective, being in and for itself of even these lifeless bodies. But, on the other hand, I must not assume that even these lifeless bodies exist only in my idea, but, since they have inscrutable qualities, and, by virtue of these, activity, I must concede to them a *being in itself* of some kind. But this very inscrutableness of the properties, while, on the one hand, it certainly points to something which exists independently of our knowledge, gives also, on the other hand, the empirical proof that our knowledge, because it consists simply in *framing ideas* by means of subjective forms, affords us always mere *phenomena*, not the true being of things. This is the explanation of the fact that in all that we know there remains hidden from us a certain something, as quite inscrutable, and we are obliged to confess that we cannot thoroughly understand even the commonest and simplest phenomena. For it is not merely the highest productions of nature, living creatures, or the *complicated* phenomena of the unorganised world that remain inscrutable to us, but even every rock-crystal, every iron-pyrite, by reason of its crystallographical, optical, chemical, and electrical properties, is to the searching consideration and investigation an abyss of incomprehensibilities and mysteries. This could not be the case if we knew things as they are in themselves; for then at least the simpler phenomena, the path to whose qualities was not barred for us by

ignorance, would necessarily be thoroughly comprehensible to us, and their whole being and nature would be able to pass over into our knowledge. Thus it lies not in the defectiveness of our acquaintance with things, but in the nature of knowledge itself. For if our perception, and consequently the whole empirical comprehension of the things that present themselves to us, is already essentially and in the main determined by our faculty of knowledge, and conditioned by its forms and functions, it cannot but be that things exhibit themselves in a manner which is quite different from their own inner nature, and therefore appear as in a mask, which allows us merely to assume what is concealed beneath it, but never to know it; hence, then, it gleams through as an inscrutable mystery, and never can the nature of anything entire and without reserve pass over into knowledge; but much less can any real thing be construed *a priori*, like a mathematical problem. Thus the empirical inscrutableness of all natural things is a proof *a posteriori* of the ideality and merely phenomenal-actuality of their empirical existence.

According to all this, upon the path of *objective knowledge*, hence starting from the *idea*, one will never get beyond the idea, *i.e.*, the phenomenon. One will thus remain at the outside of things, and will never be able to penetrate to their inner nature and investigate what they are in themselves, *i.e.*, for themselves. So far I agree with Kant. But, as the counterpart of this truth, I have given prominence to this other truth, that we are not merely the *knowing subject*, but, in another aspect, we ourselves also belong to the inner nature that is to be known, *we ourselves are the thing in itself*; that therefore a *way from within* stands open for us to that inner nature belonging to things themselves, to which we cannot penetrate *from without*, as it were a subterranean passage, a secret alliance, which, as if by treachery, places us at once within the fortress which it was impossible to take by assault from without. The thing in itself can, as such, only come into consciousness quite directly, in this way, that *it is itself conscious of itself*: to wish to know it objectively is to desire something contradictory. Everything objective is idea, therefore appearance, mere phenomenon of the brain.

Kant's chief result may in substance be thus concisely stated: "All conceptions which have not at their foundation a perception in space and time (sensuous intuition), that is to say then, which have not been drawn from such a perception, are absolutely empty, *i.e.*, give no knowledge. But

since now perception can afford us only *phenomena*, not things in themselves, we have also absolutely no knowledge of things in themselves." I grant this of everything, with the single exception of the knowledge which each of us has of his own *willing*: this is neither a perception (for all perception is spatial) nor is it empty; rather it is more real than any other. Further, it is not *a priori*, like merely formal knowledge, but entirely *a posteriori*; hence also we cannot anticipate it in the particular case, but are hereby often convicted of error concerning ourselves. In fact, our *willing* is the one opportunity which we have of understanding from within any event which exhibits itself without, consequently the one thing which is known to us *immediately*, and not, like all the rest, merely given in the idea. Here, then, lies the datum which alone is able to become the key to everything else, or, as I have said, the single narrow door to the truth. Accordingly we must learn to understand nature from ourselves, not conversely ourselves from nature. What is known to us immediately must give us the explanation of what we only know indirectly, not conversely. Do we perhaps understand the rolling of a ball when it has received an impulse more thoroughly than our movement when we feel a motive? Many may imagine so, but I say it is the reverse. Yet we shall attain to the knowledge that what is essential in both the occurrences just mentioned is identical; although identical in the same way as the lowest audible note of harmony is the same as the note of the same name ten octaves higher.

Meanwhile it should be carefully observed, and I have always kept it in mind, that even the inward experience which we have of our own will by no means affords us an exhaustive and adequate knowledge of the thing in itself. This would be the case if it were entirely an immediate experience; but it is effected in this way: the will, with and by means of the corporisation, provides itself also with an intellect (for the sake of its relations to the external world), and through this now knows itself as will in self-consciousness (the necessary counterpart of the external world); this knowledge therefore of the thing in itself is not fully adequate. First of all, it is bound to the form of the idea, it is apprehension, and as such falls asunder into subject and object. For even in self-consciousness the I is not absolutely simple, but consists of a knower, the intellect, and a known, the will. The former is not known, and the latter does not know, though both unite in the consciousness of an I. But just on this account that I is not thoroughly *intimate* with itself, as it were transparent, but is opaque, and

therefore remains a riddle to itself, thus even in inner knowledge there also exists a difference between the true being of its object and the apprehension of it in the knowing subject. Yet inner knowledge is free from two forms which belong to outer knowledge, the form of *space* and the form of *causality*, which is the means of effecting all sense-perception. On the other hand, there still remains the form of *time*, and that of being known and knowing in general. Accordingly in this inner knowledge the thing in itself has indeed in great measure thrown off its veil, but still does not yet appear quite naked. In consequence of the form of time which still adheres to it, every one knows his will only in its successive *acts*, and not as a whole, in and for itself: therefore no one knows his character *a priori*, but only learns it through experience and always incompletely. But yet the apprehension, in which we know the affections and acts of our own will, is far more immediate than any other. It is the point at which the thing in itself most directly enters the phenomenon and is most closely examined by the knowing subject; therefore the event thus intimately known is alone fitted to become the interpreter of all others.

For in every emergence of an act of will from the obscure depths of our inner being into the knowing consciousness a direct transition occurs of the thing in itself, which lies outside time, into the phenomenal world. Accordingly the act of will is indeed only the closest and most distinct *manifestation* of the thing in itself; yet it follows from this that if all other manifestations or phenomena could be known by us as directly and inwardly, we would be obliged to assert them to be that which the will is in us. Thus in this sense I teach that the inner nature of everything is *will*, and I call will the thing in itself. Kant's doctrine of the unknowableness of the thing in itself is hereby modified to this extent, that the thing in itself is only not absolutely and from the very foundation knowable, that yet by far the most immediate of its phenomena, which by this immediateness is *toto genere* distinguished from all the rest, represents it for us; and accordingly we have to refer the whole world of phenomena to that one in which the thing in itself appears in the very thinnest of veils, and only still remains phenomenon in so far as my intellect, which alone is capable of knowledge, remains ever distinguished from me as the willing subject, and moreover does not even in *inner* perfection put off the form of knowledge of *time*.

Accordingly, even after this last and furthest step, the question may still be raised, what that will, which exhibits itself in the world and as the world,

ultimately and absolutely is in itself? *i.e.*, what it is, regarded altogether apart from the fact that it exhibits itself as will, or in general *appears*, *i.e.*, in general is *known*. This question can never be answered: because, as we have said, becoming known is itself the contradictory of being in itself, and everything that is known is as such only phenomenal. But the possibility of this question shows that the thing in itself, which we know most directly in the will, may have, entirely outside all possible phenomenal appearance, ways of existing, determinations, qualities, which are absolutely unknowable and incomprehensible to us, and which remain as the nature of the thing in itself, when, as is explained in the fourth book, it has voluntarily abrogated itself as *will*, and has therefore retired altogether from the phenomenon, and for our knowledge, *i.e.*, as regards the world of phenomena, has passed into empty nothingness. If the will were simply and absolutely the thing in itself this nothing would also be *absolute*, instead of which it expressly presents itself to us there as only *relative*.

I now proceed to supplement with a few considerations pertinent to the subject the exposition given both in our second book and in the work "*Ueber den Willen in der Natur*," of the doctrine that what makes itself known to us in the most immediate knowledge as will is also that which objectifies itself at different grades in all the phenomena of this world; and I shall begin by citing a number of psychological facts which prove that first of all in our own consciousness the will always appears as primary and fundamental, and throughout asserts its superiority to the intellect, which, on the other hand, always presents itself as secondary, subordinate, and conditioned. This proof is the more necessary as all philosophers before me, from the first to the last, place the true being or the kernel of man in the *knowing* consciousness, and accordingly have conceived and explained the I, or, in the case of many of them, its transcendental hypostasis called soul, as primarily and essentially *knowing*, nay, *thinking*, and only in consequence of this, secondarily and derivatively, as *willing*. This ancient and universal radical error, this enormous πρωτον ψευδος and fundamental ὑστερον προτερον, must before everything be set aside, and instead of it the true state of the case must be brought to perfectly distinct consciousness. Since, however, this is done here for the first time, after thousands of years of philosophising, some fulness of statement will be appropriate. The remarkable phenomenon, that in this most essential point all philosophers have erred, nay, have exactly reversed the truth, might, especially in the

case of those of the Christian era, be partly explicable from the fact that they all had the intention of presenting man as distinguished as widely as possible from the brutes, yet at the same time obscurely felt that the difference between them lies in the intellect, not in the will; whence there arose unconsciously within them an inclination to make the intellect the essential and principal thing, and even to explain volition as a mere function of the intellect. Hence also the conception of a soul is not only inadmissible, because it is a transcendent hypostasis, as is proved by the "Critique of Pure Reason," but it becomes the source of irremediable errors, because in its "simple substance" it establishes beforehand an indivisible unity of knowledge and will, the separation of which is just the path to the truth. That conception must therefore appear no more in philosophy, but may be left to German doctors and physiologists, who, after they have laid aside scalpel and spattle, amuse themselves by philosophising with the conceptions they received when they were confirmed. They might certainly try their luck in England. The French physiologists and zootomists have (till lately) kept themselves free from that reproach.

The first consequence of their common fundamental error, which is very inconvenient to all these philosophers, is this: since in death the knowing consciousness obviously perishes, they must either allow death to be the annihilation of the man, to which our inner being is opposed, or they must have recourse to the assumption of a continued existence of the knowing consciousness, which requires a strong faith, for his own experience has sufficiently proved to every one the thorough and complete dependence of the knowing consciousness upon the brain, and one can just as easily believe in digestion without a stomach as in a knowing consciousness without a brain. My philosophy alone leads out of this dilemma, for it for the first time places the true being of man not in the consciousness but in the will, which is not essentially bound up with consciousness, but is related to consciousness, *i.e.*, to knowledge, as substance to accident, as something illuminated to the light, as the string to the resounding-board, and which enters consciousness from within as the corporeal world does from without. Now we can comprehend the indestructibleness of this our real kernel and true being, in spite of the evident ceasing of consciousness in death, and the corresponding non-existence of it before birth. For the intellect is as perishable as the brain, whose product or rather whose action it is. But the

brain, like the whole organism, is the product or phenomenon, in short, the subordinate of the will, which alone is imperishable.

Chapter XIX.[30] On The Primacy Of The Will In Self-Consciousness.

The will, as the thing in itself, constitutes the inner, true, and indestructible nature of man; in itself, however, it is unconscious. For consciousness is conditioned by the intellect, and the intellect is a mere accident of our being; for it is a function of the brain, which, together with the nerves and spinal cord connected with it, is a mere fruit, a product, nay, so far, a parasite of the rest of the organism; for it does not directly enter into its inner constitution, but merely serves the end of self-preservation by regulating the relations of the organism to the external world. The organism itself, on the other hand, is the visibility, the objectivity, of the individual will, the image of it as it presents itself in that very brain (which in the first book we learned to recognise as the condition of the objective world in general), therefore also brought about by its forms of knowledge, space, time, and causality, and consequently presenting itself as extended, successively acting, and material, *i.e.*, as something operative or efficient. The members are both directly felt and also perceived by means of the senses only in the brain. According to this one may say: The intellect is the secondary phenomenon; the organism the primary phenomenon, that is, the immediate manifestation of the will; the will is metaphysical, the intellect physical; — the intellect, like its objects, is merely phenomenal appearance; the will alone is the thing in itself. Then, in a more and more *figurative sense*, thus by way of simile: The will is the substance of man, the intellect the accident; the will is the matter, the intellect is the form; the will is warmth, the intellect is light.

We shall now first of all verify and also elucidate this thesis by the following facts connected with the inner life of man; and on this opportunity perhaps more will be done for the knowledge of the inner man than is to be found in many systematic psychologies.

1. Not only the consciousness of other things, *i.e.*, the apprehension of the external world, but also *self-consciousness*, contains, as was mentioned already above, a knower and a known; otherwise it would not be *consciousness*. For *consciousness* consists in knowing; but knowing requires a knower and a known; therefore there could be no self-consciousness if there were not in it also a known opposed to the knower

and different from it. As there can be no object without a subject, so also there can be no subject without an object, *i.e.*, no knower without something different from it which is known. Therefore a consciousness which is through and through pure intelligence is impossible. The intelligence is like the sun, which does not illuminate space if there is no object from which its rays are reflected. The knower himself, as such, cannot be known; otherwise he would be the known of another knower. But now, as the *known* in self-consciousness we find exclusively the *will*. For not merely willing and purposing in the narrowest sense, but also all striving, wishing, shunning, hoping, fearing, loving, hating, in short, all that directly constitutes our own weal and woe, desire and aversion, is clearly only affection of the will, is a moving, a modification of willing and not-willing, is just that which, if it takes outward effect, exhibits itself as an act of will proper.[31] In all knowledge, however, the known is first and essential, not the knower; for the former is the πρωτοτυπος, the latter the εκτυπος. Therefore in self-consciousness also the known, thus the will, must be what is first and original; the knower, on the other hand, only what is secondary, that which has been added, the mirror. They are related very much as the luminous to the reflecting body; or, again, as the vibrating strings to the resounding-board, in which case the note produced would be consciousness. We may also regard the plant as a like symbol of consciousness. It has, we know, two poles, the root and the corona: the former struggling into darkness, moisture, and cold, the latter into light, dryness, and warmth; then, as the point of indifference of the two poles, where they part asunder, close to the ground, the collum (*rhizoma*, *le collet*). The root is what is essential, original, perennial, the death of which involves that of the corona, is thus the primary; the corona, on the other hand, is the ostensible, but it has sprung from something else, and it passes away without the root dying; it is thus secondary. The root represents the will, the corona the intellect, and the point of indifference of the two, the collum, would be the *I*, which, as their common termination, belongs to both. This I is the *pro tempore* identical subject of knowing and willing, whose identity I called in my very first essay (on the principle of sufficient reason), and in my first philosophical wonder, the miracle κατ εξοχην. It is the temporal starting-point and connecting-link of the whole phenomenon, *i.e.*, of the objectification of the will: it conditions indeed the phenomenon, but is also conditioned by it. This comparison may even be carried to the individual

nature of men. As a large corona commonly springs only from a large root, so the greatest intellectual capabilities are only found in connection with a vehement and passionate will. A genius of a phlegmatic character and weak passions would resemble those succulent plants that, with a considerable corona consisting of thick leaves, have very small roots; will not, however, be found. That vehemence of will and passionateness of character are conditions of heightened intelligence exhibits itself physiologically through the fact that the activity of the brain is conditioned by the movement which the great arteries running towards the *basis cerebri* impart to it with each pulsation; therefore an energetic pulse, and even, according to Bichat, a short neck, is a requisite of great activity of the brain. But the opposite of the above certainly occurs: vehement desires, passionate, violent character, along with weak intellect, *i.e.*, a small brain of bad conformation in a thick skull. This is a phenomenon as common as it is repulsive: we might perhaps compare it to beetroot.

2. But in order not merely to describe consciousness figuratively, but to know it thoroughly, we have first of all to find out what appears in the same way in every consciousness, and therefore, as the common and constant element, will also be the essential. Then we shall consider what distinguishes *one* consciousness from another, which accordingly will be the adventitious and secondary element.

Consciousness is positively only known to us as a property of animal nature; therefore we must not, and indeed cannot, think of it otherwise than as *animal consciousness*, so that this expression is tautological. Now, that which in *every* animal consciousness, even the most imperfect and the weakest, is always present, nay, lies at its foundation, is an immediate sense of *longing*, and of the alternate satisfaction and non-satisfaction of it, in very different degrees. This we know to a certain extent *a priori*. For marvellously different as the innumerable species of animals are, and strange as some new form, never seen before, appears to us, we yet assume beforehand its inmost nature, with perfect certainty, as well known, and indeed fully confided to us. We know that the animal *wills*, indeed also *what* it wills, existence, well-being, life, and propagation; and since in this we presuppose with perfect certainty identity with us, we do not hesitate to attribute to it unchanged all the affections of will which we know in ourselves, and speak at once of its desire, aversion, fear, anger, hatred, love, joy, sorrow, longing, &c. On the other hand, whenever phenomena of mere

knowledge come to be spoken of we fall at once into uncertainty. We do not venture to say that the animal conceives, thinks, judges, knows: we only attribute to it with certainty ideas in general; because without them its *will* could not have those emotions referred to above. But with regard to the definite manner of knowing of the brutes and the precise limits of it in a given species, we have only indefinite conceptions, and make conjectures. Hence our understanding with them is also often difficult, and is only brought about by skill, in consequence of experience and practice. Here then lie distinctions of consciousness. On the other hand, a longing, desiring, wishing, or a detesting, shunning, and not wishing, is proper to every consciousness: man has it in common with the polyp. This is accordingly the essential element in and the basis of every consciousness. The difference of the manifestations of this in the different species of animal beings depends upon the various extension of their sphere of knowledge, in which the motives of those manifestations lie. We understand directly from our own nature all actions and behaviour of the brutes which express movements of the will; therefore, so far, we sympathise with them in various ways. On the other hand, the gulf between us and them results simply and solely from the difference of intellect. The gulf which lies between a very sagacious brute and a man of very limited capacity is perhaps not much greater than that which exists between a blockhead and a man of genius; therefore here also the resemblance between them in another aspect, which springs from the likeness of their inclinations and emotions, and assimilates them again to each other, sometimes appears with surprising prominence, and excites astonishment. This consideration makes it clear that in all animal natures the *will* is what is primary and substantial, the *intellect* again is secondary, adventitious, indeed a mere tool for the service of the former, and is more or less complete and complicated, according to the demands of this service. As a species of animals is furnished with hoofs, claws, hands, wings, horns, or teeth according to the aims of its will, so also is it furnished with a more or less developed brain, whose function is the intelligence necessary for its endurance. The more complicated the organisation becomes, in the ascending series of animals, the more numerous also are its wants, and the more varied and specially determined the objects which are capable of satisfying them; hence the more complicated and distant the paths by which these are to be obtained, which must now be all known and found: therefore in the same proportion the

ideas of the animal must be more versatile, accurate, definite, and connected, and also its attention must be more highly strung, more sustained, and more easily roused, consequently its intellect must be more developed and perfect. Accordingly we see the organ of intelligence, the cerebral system, together with all the organs of sense, keep pace with the increasing wants and the complication of the organism; and the increase of the part of consciousness that has to do with ideas (as opposed to the willing part) exhibits itself in a bodily form in the ever-increasing proportion of the brain in general to the rest of the nervous system, and of the cerebrum to the cerebellum; for (according to Flourens) the former is the workshop of ideas, while the latter is the disposer and orderer of movements. The last step which nature has taken in this respect is, however, disproportionately great. For in man not only does the faculty of ideas of *perception*, which alone existed hitherto, reach the highest degree of perfection, but the *abstract* idea, thought, *i.e.*, *reason*, and with it reflection, is added. Through this important advance of the intellect, thus of the secondary part of consciousness, it now gains a preponderance over the primary part, in so far as it becomes henceforward the predominantly active part. While in the brute the immediate sense of its satisfied or unsatisfied desire constitutes by far the most important part of its consciousness, and the more so indeed the lower the grade of the animal, so that the lowest animals are only distinguished from plants by the addition of a dull idea, in man the opposite is the case. Vehement as are his desires, even more vehement than those of any brute, rising to the level of passions, yet his consciousness remains continuously and predominantly occupied and filled with ideas and thoughts. Without doubt this has been the principal occasion of that fundamental error of all philosophers on account of which they make thought that which is essential and primary in the so-called soul, *i.e.*, in the inner or spiritual life of man, always placing it first, but will, as a mere product of thought, they regard as only a subordinate addition and consequence of it. But if willing merely proceeded from knowing, how could the brutes, even the lower grades of them, with so very little knowledge, often show such an unconquerable and vehement will? Accordingly, since that fundamental error of the philosophers makes, as it were, the accident the substance, it leads them into mistaken paths, which there is afterwards no way of getting out of. Now this relative predominance of the *knowing* consciousness over the *desiring*,

consequently of the secondary part over the primary, which appears in man, may, in particular exceptionally favoured individuals, go so far that at the moments of its highest ascendancy, the secondary or knowing part of consciousness detaches itself altogether from the willing part, and passes into free activity for itself, *i.e.*, untouched by the will, and consequently no longer serving it. Thus it becomes purely objective, and the clear mirror of the world, and from it the conceptions of genius then arise, which are the subject of our third book.

3. If we run through the series of grades of animals downwards, we see the intellect always becoming weaker and less perfect, but we by no means observe a corresponding degradation of the will. Rather it retains everywhere its identical nature and shows itself in the form of great attachment to life, care for the individual and the species, egoism and regardlessness of all others, together with the emotions that spring from these. Even in the smallest insect the will is present, complete and entire; it wills what it wills as decidedly and completely as the man. The difference lies merely in *what* it wills, *i.e.*, in the motives, which, however, are the affair of the intellect. It indeed, as the secondary part of consciousness, and bound to the bodily organism, has innumerable degrees of completeness, and is in general essentially limited and imperfect. The *will*, on the contrary, as original and the thing in itself, can never be imperfect, but every act of will is all that it can be. On account of the simplicity which belongs to the will as the thing in itself, the metaphysical in the phenomenon, its nature admits of no degrees, but is always completely itself. Only its *excitement* has degrees, from the weakest inclination to the passion, and also its susceptibility to excitement, thus its vehemence from the phlegmatic to the choleric temperament. The *intellect*, on the other hand, has not merely degrees of *excitement*, from sleepiness to being in the vein, and inspiration, but also degrees of its nature, of the completeness of this, which accordingly rises gradually from the lowest animals, which can only obscurely apprehend, up to man, and here again from the fool to the genius. The *will* alone is everywhere completely itself. For its function is of the utmost simplicity; it consists in willing and not willing, which goes on with the greatest ease, without effort, and requires no practice. Knowing, on the contrary, has multifarious functions, and never takes place entirely without effort, which is required to fix the attention and to make clear the object,

and at a higher stage is certainly needed for thinking and deliberation; therefore it is also capable of great improvement through exercise and education. If the intellect presents a simple, perceptible object to the will, the latter expresses at once its approval or disapproval of it, and this even if the intellect has laboriously inquired and pondered, in order from numerous data, by means of difficult combinations, ultimately to arrive at the conclusion as to which of the two seems to be most in conformity with the interests of the will. The latter has meanwhile been idly resting, and when the conclusion is arrived at it enters, as the Sultan enters the Divan, merely to express again its monotonous approval or disapproval, which certainly may vary in degree, but in its nature remains always the same.

This fundamentally different nature of the will and the intellect, the essential simplicity and originality of the former, in contrast to the complicated and secondary character of the latter, becomes still more clear to us if we observe their remarkable interaction within us, and now consider in the particular case, how the images and thoughts which arise in the intellect move the will, and how entirely separated and different are the parts which the two play. We can indeed perceive this even in actual events which excite the will in a lively manner, while primarily and in themselves they are merely objects of the intellect. But, on the one hand, it is here not so evident that this reality primarily existed only in the intellect; and, on the other hand, the change does not generally take place so rapidly as is necessary if the thing is to be easily surveyed, and thereby become thoroughly comprehensible. Both of these conditions, however, are fulfilled if it is merely thoughts and phantasies which we allow to act on the will. If, for example, alone with ourselves, we think over our personal circumstances, and now perhaps vividly present to ourselves the menace of an actually present danger and the possibility of an unfortunate issue, anxiety at once compresses the heart, and the blood ceases to circulate in the veins. But if then the intellect passes to the possibility of an opposite issue, and lets the imagination picture the long hoped for happiness thereby attained, all the pulses quicken at once with joy and the heart feels light as a feather, till the intellect awakes from its dream. Thereupon, suppose that an occasion should lead the memory to an insult or injury once suffered long ago, at once anger and bitterness pour into the breast that was but now at peace. But then arises, called up by accident, the image of a long-lost love, with which the whole romance and its magic scenes is connected; then that

anger will at once give place to profound longing and sadness. Finally, if there occurs to us some former humiliating incident, we shrink together, would like to sink out of sight, blush with shame, and often try forcibly to distract and divert our thoughts by some loud exclamation, as if to scare some evil spirit. One sees, the intellect plays, and the will must dance to it. Indeed the intellect makes the will play the part of a child which is alternately thrown at pleasure into joyful or sad moods by the chatter and tales of its nurse. This depends upon the fact that the will is itself without knowledge, and the understanding which is given to it is without will. Therefore the former is like a body which is moved, the latter like the causes which set it in motion, for it is the medium of motives. Yet in all this the primacy of the will becomes clear again, if this will, which, as we have shown, becomes the sport of the intellect as soon as it allows the latter to control it, once makes its supremacy in the last instance felt by prohibiting the intellect from entertaining certain ideas, absolutely preventing certain trains of thought from arising, because it knows, *i.e.*, learns from that very intellect, that they would awaken in it some one of the emotions set forth above. It now bridles the intellect, and compels it to turn to other things. Hard as this often may be, it must yet be accomplished as soon as the will is in earnest about it, for the resistance in this case does not proceed from the intellect, which always remains indifferent, but from the will itself, which in one respect has an inclination towards an idea that in another respect it abhors. It is in itself interesting to the will simply because it excites it, but at the same time abstract knowledge tells it that this idea will aimlessly cause it a shock of painful or unworthy emotion: it now decides in conformity with this abstract knowledge, and compels the obedience of the intellect. This is called "being master of oneself." Clearly the master here is the will, the servant the intellect, for in the last instance the will always keeps the upper hand, and therefore constitutes the true core, the inner being of man. In this respect the title Ηγεμονικον would belong to the *will*; yet it seems, on the other hand, to apply to the *intellect*, because it is the leader and guide, like the *valet de place* who conducts a stranger. In truth, however, the happiest figure of the relation of the two is the strong blind man who carries on his shoulders the lame man who can see.

The relation of the will to the intellect here explained may also be further recognised in the fact that the intellect is originally entirely a stranger to the purposes of the will. It supplies the motives to the will, but it only learns

afterwards, completely *a posteriori*, how they have affected it, as one who makes a chemical experiment applies the reagents and awaits the result. Indeed the intellect remains so completely excluded from the real decisions and secret purposes of its own will that sometimes it can only learn them like those of a stranger, by spying upon them and surprising them, and must catch the will in the act of expressing itself in order to get at its real intentions. For example, I have conceived a plan, about which, however, I have still some scruple, but the feasibleness of which, as regards its possibility, is completely uncertain, for it depends upon external and still undecided circumstances. It would therefore certainly be unnecessary to come to a decision about it at present, and so for the time I leave the matter as it is. Now in such a case I often do not know how firmly I am already attached to that plan in secret, and how much, in spite of the scruple, I wish to carry it out: that is, my intellect does not know. But now only let me receive news that it is practicable, at once there rises within me a jubilant, irresistible gladness, that passes through my whole being and takes permanent possession of it, to my own astonishment. For now my intellect learns for the first time how firmly my will had laid hold of that plan, and how thoroughly the plan suited it, while the intellect had regarded it as entirely problematical, and had with difficulty been able to overcome that scruple. Or in another case, I have entered eagerly into a contract which I believed to be very much in accordance with my wishes. But as the matter progresses the disadvantages and burdens of it are felt, and I begin to suspect that I even repent of what I so eagerly pursued; yet I rid myself of this feeling by assuring myself that even if I were not bound I would follow the same course. Now, however, the contract is unexpectedly broken by the other side, and I perceive with astonishment that this happens to my great satisfaction and relief. Often we don't know what we wish or what we fear. We may entertain a wish for years without even confessing it to ourselves, or even allowing it to come to clear consciousness; for the intellect must know nothing about it, because the good opinion which we have of ourselves might thereby suffer. But if it is fulfilled we learn from our joy, not without shame, that we have wished this. For example, the death of a near relation whose heir we are. And sometimes we do not know what we really fear, because we lack the courage to bring it to distinct consciousness. Indeed we are often in error as to the real motive from which we have done something or left it undone, till at last perhaps an accident discovers to us

the secret, and we know that what we have held to be the motive was not the true one, but another which we had not wished to confess to ourselves, because it by no means accorded with the good opinion we entertained of ourselves. For example, we refrain from doing something on purely moral grounds, as we believe, but afterwards we discover that we were only restrained by fear, for as soon as all danger is removed we do it. In particular cases this may go so far that a man does not even guess the true motive of his action, nay, does not believe himself capable of being influenced by such a motive; and yet it is the true motive of his action. We may remark in passing that in all this we have a confirmation and explanation of the rule of Larochefoucauld: "*L'amour-propre est plus habile que le plus habile homme du monde;*" nay, even a commentary on the Delphic γνωθι σαυτον and its difficulty. If now, on the contrary, as all philosophers imagine, the intellect constituted our true nature and the purposes of the will were a mere result of knowledge, then only the motive from which we imagined that we acted would be decisive of our moral worth; in analogy with the fact that the intention, not the result, is in this respect decisive. But really then the distinction between imagined and true motive would be impossible. Thus all cases here set forth, to which every one who pays attention may observe analogous cases in himself, show us how the intellect is so strange to the will that it is sometimes even mystified by it: for it indeed supplies it with motives, but does not penetrate into the secret workshop of its purposes. It is indeed a confidant of the will, but a confidant that is not told everything. This is also further confirmed by the fact, which almost every one will some time have the opportunity of observing in himself, that sometimes the intellect does not thoroughly trust the will. If we have formed some great and bold purpose, which as such is yet really only a promise made by the will to the intellect, there often remains within us a slight unconfessed doubt whether we are quite in earnest about it, whether in carrying it out we will not waver or draw back, but will have sufficient firmness and persistency to fulfil it. It therefore requires the deed to convince us ourselves of the sincerity of the purpose.

All these facts prove the absolute difference of the will and the intellect, the primacy of the former and the subordinate position of the latter.

4. The *intellect* becomes tired; the *will* is never tired. After sustained work with the head we feel the tiredness of the brain, just like that of the arm after sustained bodily work. All *knowing* is accompanied with effort;

willing, on the contrary, is our very nature, whose manifestations take place without any weariness and entirely of their own accord. Therefore, if our will is strongly excited, as in all emotions, thus in anger, fear, desire, grief, &c., and we are now called upon to know, perhaps with the view of correcting the motives of that emotion, the violence which we must do ourselves for this purpose is evidence of the transition from the original natural activity proper to ourselves to the derived, indirect, and forced activity. For the will alone is αυτοματος, and therefore ακαματος και αγηρατος ηματα παντα (*lassitudinis et senii expers in sempiternum*). It alone is active without being called upon, and therefore often too early and too much, and it knows no weariness. Infants who scarcely show the first weak trace of intelligence are already full of self-will: through unlimited, aimless roaring and shrieking they show the pressure of will with which they swell, while their willing has yet no object, *i.e.*, they will without knowing what they will. What Cabanis has observed is also in point here: "*Toutes ces passions, qui se succèdent d'une mannière si rapide, et se peignent avec tant de naïveté, sur le visage mobile des enfants. Tandis que les faibles muscles de leurs bras et de leurs jambes savent encore a peine former quelque mouvemens indécis, les muscles de la face expriment déjà par des mouvemens distincts presque toute la suite des affections générales propres a la nature humaine: et l'observateur attentif reconnait facilement dans ce tableau les traits caractéristiques de l'homme futur*" (*Rapports du Physique et Moral*, vol. i. p. 123). The intellect, on the contrary, develops slowly, following the completion of the brain and the maturity of the whole organism, which are its conditions, just because it is merely a somatic function. It is because the brain attains its full size in the seventh year that from that time forward children become so remarkably intelligent, inquisitive, and reasonable. But then comes puberty; to a certain extent it affords a support to the brain, or a resounding-board, and raises the intellect at once by a large step, as it were by an octave, corresponding to the lowering of the voice by that amount. But at once the animal desires and passions that now appear resist the reasonableness that has hitherto prevailed and to which they have been added. Further evidence is given of the indefatigable nature of the will by the fault which is, more or less, peculiar to all men by nature, and is only overcome by education — *precipitation*. It consists in this, that the will hurries to its work before the time. This work is the purely active and executive part, which ought only to

begin when the explorative and deliberative part, thus the work of knowing, has been completely and thoroughly carried out. But this time is seldom waited for. Scarcely are a few data concerning the circumstances before us, or the event that has occurred, or the opinion of others conveyed to us, superficially comprehended and hastily gathered together by knowledge, than from the depths of our being the will, always ready and never weary, comes forth unasked, and shows itself as terror, fear, hope, joy, desire, envy, grief, zeal, anger, or courage, and leads to rash words and deeds, which are generally followed by repentance when time has taught us that the hegemonicon, the intellect, has not been able to finish half its work of comprehending the circumstances, reflecting on their connection, and deciding what is prudent, because the will did not wait for it, but sprang forward long before its time with "Now it is my turn!" and at once began the active work, without the intellect being able to resist, as it is a mere slave and bondman of the will, and not, like it, αυτοματος, nor active from its own power and its own impulse; therefore it is easily pushed aside and silenced by a nod of the will, while on its part it is scarcely able, with the greatest efforts, to bring the will even to a brief pause, in order to speak. This is why the people are so rare, and are found almost only among Spaniards, Turks, and perhaps Englishmen, who even under circumstances of provocation *keep the head uppermost*, imperturbably proceed to comprehend and investigate the state of affairs, and when others would already be beside themselves, *con mucho sosiego*, still ask further questions, which is something quite different from the indifference founded upon apathy and stupidity of many Germans and Dutchmen. Iffland used to give an excellent representation of this admirable quality, as Hetmann of the Cossacks, in Benjowski, when the conspirators have enticed him into their tent and hold a rifle to his head, with the warning that they will fire it if he utters a cry, Iffland blew into the mouth of the rifle to try whether it was loaded. Of ten things that annoy us, nine would not be able to do so if we understood them thoroughly in their causes, and therefore knew their necessity and true nature; but we would do this much oftener if we made them the object of reflection before making them the object of wrath and indignation. For what bridle and bit are to an unmanageable horse the intellect is for the will in man; by this bridle it must be controlled by means of instruction, exhortation, culture, &c., for in itself it is as wild and impetuous an impulse as the force that appears in the descending waterfall,

nay, as we know, it is at bottom identical with this. In the height of anger, in intoxication, in despair, it has taken the bit between its teeth, has run away, and follows its original nature. In the *Mania sine delirio* it has lost bridle and bit altogether, and shows now most distinctly its original nature, and that the intellect is as different from it as the bridle from the horse. In this condition it may also be compared to a clock which, when a certain screw is taken away, runs down without stopping.

Thus this consideration also shows us the will as that which is original, and therefore metaphysical; the intellect, on the other hand, as something subordinate and physical. For as such the latter is, like everything physical, subject to *vis inertiæ*, consequently only active if it is set agoing by something else, the will, which rules it, manages it, rouses it to effort, in short, imparts to it the activity which does not originally reside in it. Therefore it willingly rests whenever it is permitted to do so, often declares itself lazy and disinclined to activity; through continued effort it becomes weary to the point of complete stupefaction, is exhausted, like the voltaic pile, through repeated shocks. Hence all continuous mental work demands pauses and rest, otherwise stupidity and incapacity ensue, at first of course only temporarily; but if this rest is persistently denied to the intellect it will become excessively and continuously fatigued, and the consequence is a permanent deterioration of it, which in an old man may pass into complete incapacity, into childishness, imbecility, and madness. It is not to be attributed to age in and for itself, but to long-continued tyrannical over-exertion of the intellect or brain, if this misfortune appears in the last years of life. This is the explanation of the fact that Swift became mad, Kant became childish, Walter Scott, and also Wordsworth, Southey, and many *minorum gentium*, became dull and incapable. Goethe remained to the end clear, strong, and active-minded, because he, who was always a man of the world and a courtier, never carried on his mental occupations with self-compulsion. The same holds good of Wieland and of Kuebel, who lived to the age of ninety-one, and also of Voltaire. Now all this proves how very subordinate and physical and what a mere tool the intellect is. Just on this account it requires, during almost a third part of its lifetime, the entire suspension of its activity in sleep, *i.e.*, the rest of the brain, of which it is the mere function, and which therefore just as truly precedes it as the stomach precedes digestion, or as a body precedes its impulsion, and with which in old age it flags and decays. The will, on the contrary, as the thing in itself, is

never lazy, is absolutely untiring, its activity is its essence, it never ceases willing, and when, during deep sleep, it is forsaken of the intellect, and therefore cannot act outwardly in accordance with motives, it is active as the vital force, cares the more uninterruptedly for the inner economy of the organism, and as *vis naturæ medicatrix* sets in order again the irregularities that have crept into it. For it is not, like the intellect, a function of the body; *but the body is its function*; therefore it is, *ordine rerum*, prior to the body, as its metaphysical substratum, as the in-itself of its phenomenal appearance. It shares its unwearying nature, for the time that life lasts, with the heart, that *primum mobile* of the organism, which has therefore become its symbol and synonym. Moreover, it does not disappear in the old man, but still continues to will what it has willed, and indeed becomes firmer, more inflexible, than it was in youth, more implacable, self-willed, and unmanageable, because the intellect has become less susceptible: therefore in old age the man can perhaps only be matched by taking advantage of the weakness of his intellect.

Moreover, the prevailing *weakness* and *imperfection* of the intellect, as it is shown in the want of judgment, narrow-mindedness, perversity, and folly of the great majority of men, would be quite inexplicable if the intellect were not subordinate, adventitious, and merely instrumental, but the immediate and original nature of the so-called soul, or in general of the inner man: as all philosophers have hitherto assumed it to be. For how could the original nature in its immediate and peculiar function so constantly err and fail? The *truly* original in human consciousness, the *willing*, always goes on with perfect success; every being wills unceasingly, capably, and decidedly. To regard the immorality in the will as an imperfection of it would be a fundamentally false point of view. For morality has rather a source which really lies above nature, and therefore its utterances are in contradiction with it. Therefore morality is in direct opposition to the natural will, which in itself is completely egoistic; indeed the pursuit of the path of morality leads to the abolition of the will. On this subject I refer to our fourth book and to my prize essay, "*Ueber das Fundament der Moral*."

5. That the *will* is what is real and essential in man, and the *intellect* only subordinate, conditioned, and produced, is also to be seen in the fact that the latter can carry on its function with perfect purity and correctness only so long as the will is silent and pauses. On the other hand, the function of the

intellect is disturbed by every observable excitement of the will, and its result is falsified by the intermixture of the latter; but the converse does not hold, that the intellect should in the same way be a hindrance to the will. Thus the moon cannot shine when the sun is in the heavens, but when the moon is in the heavens it does not prevent the sun from shining.

A great *fright* often deprives us of our senses to such an extent that we are petrified, or else do the most absurd things; for example, when fire has broken out run right into the flames. *Anger* makes us no longer know what we do, still less what we say. *Zeal*, therefore called blind, makes us incapable of weighing the arguments of others, or even of seeking out and setting in order our own. *Joy* makes us inconsiderate, reckless, and foolhardy, and *desire* acts almost in the same way. *Fear* prevents us from seeing and laying hold of the resources that are still present, and often lie close beside us. Therefore for overcoming sudden dangers, and also for fighting with opponents and enemies, the most essential qualifications are *coolness and presence of mind*. The former consists in the silence of the will so that the intellect can act; the latter in the undisturbed activity of the intellect under the pressure of events acting on the will; therefore the former is the condition of the latter, and the two are nearly related; they are seldom to be found, and always only in a limited degree. But they are of inestimable advantage, because they permit the use of the intellect just at those times when we stand most in need of it, and therefore confer decided superiority. He who is without them only knows what he should have done or said when the opportunity has passed. It is very appropriately said of him who is violently moved, *i.e.*, whose will is so strongly excited that it destroys the purity of the function of the intellect, he is *disarmed*; for the correct knowledge of the circumstances and relations is our defence and weapon in the conflict with things and with men. In this sense Balthazar Gracian says: “*Es la passion enemiga declarada de la cordura*” (Passion is the declared enemy of prudence). If now the intellect were not something completely different from the will, but, as has been hitherto supposed, knowing and willing had the same root, and were equally original functions of an absolutely simple nature, then with the rousing and heightening of the will, in which the emotion consists, the intellect would necessarily also be heightened; but, as we have seen, it is rather hindered and depressed by this; whence the ancients called emotion *animi perturbatio*. The intellect is really like the reflecting surface of water, but the water itself is like the will,

whose disturbance therefore at once destroys the clearness of that mirror and the distinctness of its images. The *organism* is the will itself, is embodied will, *i.e.*, will objectively perceived in the brain. Therefore many of its functions, such as respiration, circulation, secretion of bile, and muscular power, are heightened and accelerated by the pleasurable, and in general the healthy, emotions. The *intellect*, on the other hand, is the mere function of the brain, which is only nourished and supported by the organism as a parasite. Therefore every perturbation of the *will*, and with it of the *organism*, must disturb and paralyse the function of the brain, which exists for itself and for no other wants than its own, which are simply rest and nourishment.

But this disturbing influence of the activity of the will upon the intellect can be shown, not only in the perturbations brought about by emotions, but also in many other, more gradual, and therefore more lasting falsifications of thought by our inclinations. *Hope* makes us regard what we wish, and *fear* what we are apprehensive of, as probable and near, and both exaggerate their object. Plato (according to Ælian, V.H., 13, 28) very beautifully called hope the dream of the waking. Its nature lies in this, that the will, when its servant the intellect is not able to produce what it wishes, obliges it at least to picture it before it, in general to undertake the roll of comforter, to appease its lord with fables, as a nurse a child, and so to dress these out that they gain an appearance of likelihood. Now in this the intellect must do violence to its own nature, which aims at the truth, for it compels it, contrary to its own laws, to regard as true things which are neither true nor probable, and often scarcely possible, only in order to appease, quiet, and send to sleep for a while the restless and unmanageable *will*. Here we see clearly who is master and who is servant. Many may well have observed that if a matter which is of importance to them may turn out in several different ways, and they have brought all of these into one disjunctive judgment which in their opinion is complete, the actual result is yet quite another, and one wholly unexpected by them: but perhaps they will not have considered this, that this result was then almost always the one which was unfavourable to them. The explanation of this is, that while their *intellect* intended to survey the possibilities completely, the worst of all remained quite invisible to it; because the *will*, as it were, covered it with its hand, that is, it so mastered the intellect that it was quite incapable of glancing at the worst case of all, although, since it actually came to pass, this was also

the most probable case. Yet in very melancholy dispositions, or in those that have become prudent through experience like this, the process is reversed, for here apprehension plays the part which was formerly played by hope. The first appearance of danger throws them into groundless anxiety. If the intellect begins to investigate the matter it is rejected as incompetent, nay, as a deceitful sophist, because the heart is to be believed, whose fears are now actually allowed to pass for arguments as to the reality and greatness of the danger. So then the intellect dare make no search for good reasons on the other side, which, if left to itself, it would soon recognise, but is obliged at once to picture to them the most unfortunate issue, even if it itself can scarcely think this issue possible:

"Such as we know is false, yet dread in sooth,
Because the worst is ever nearest truth."
— Byron (*Lara*, c. 1).

Love and *hate* falsify our judgment entirely. In our enemies we see nothing but faults — in our loved ones nothing but excellences, and even their faults appear to us amiable. Our *interest*, of whatever kind it may be, exercises a like secret power over our judgment; what is in conformity with it at once seems to us fair, just, and reasonable; what runs contrary to it presents itself to us, in perfect seriousness, as unjust and outrageous, or injudicious and absurd. Hence so many prejudices of position, profession, nationality, sect, and religion. A conceived hypothesis gives us lynx-eyes for all that confirms it, and makes us blind to all that contradicts it. What is opposed to our party, our plan, our wish, our hope, we often cannot comprehend and grasp at all, while it is clear to every one else; but what is favourable to these, on the other hand, strikes our eye from afar. What the heart opposes the head will not admit. We firmly retain many errors all through life, and take care never to examine their ground, merely from a fear, of which we ourselves are conscious, that we might make the discovery that we had so long believed and so often asserted what is false. Thus then is the intellect daily befooled and corrupted by the impositions of inclination. This has been very beautifully expressed by Bacon of Verulam in the words: *Intellectus* luminis sicci *non est; sed recipit infusionem a voluntate et affectibus: id quod generat ad quod vult scientias: quod enim mavult homo, id potius credit. Innumeris modis, iisque interdum imperceptibilibus, affectus intellectum imbuit et inficit* (*Org. Nov.*, i. 14). Clearly it is also this that opposes all new fundamental opinions in the

sciences and all refutations of sanctioned errors, for one will not easily see the truth of that which convicts one of incredible want of thought. It is explicable, on this ground alone, that the truths of Goethe's doctrine of colours, which are so clear and simple, are still denied by the physicists; and thus Goethe himself has had to learn what a much harder position one has if one promises men instruction than if one promises them amusement. Hence it is much more fortunate to be born a poet than a philosopher. But the more obstinately an error was held by the other side, the more shameful does the conviction afterwards become. In the case of an overthrown system, as in the case of a conquered army, the most prudent is he who first runs away from it.

A trifling and absurd, but striking example of that mysterious and immediate power which the will exercises over the intellect, is the fact that in doing accounts we make mistakes much oftener in our own favour than to our disadvantage, and this without the slightest dishonest intention, merely from the unconscious tendency to diminish our *Debit* and increase our *Credit*.

Lastly, the fact is also in point here, that when advice is given the slightest aim or purpose of the adviser generally outweighs his insight, however great it may be; therefore we dare not assume that he speaks from the latter when we suspect the existence of the former. How little perfect sincerity is to be expected even from otherwise honest persons whenever their interests are in any way concerned we can gather from the fact that we so often deceive ourselves when hope bribes us, or fear befools us, or suspicion torments us, or vanity flatters us, or an hypothesis blinds us, or a small aim which is close at hand injures a greater but more distant one; for in this we see the direct and unconscious disadvantageous influence of the will upon knowledge. Accordingly it ought not to surprise us if in asking advice the will of the person asked directly dictates the answer even before the question could penetrate to the forum of his judgment.

I wish in a single word to point out here what will be fully explained in the following book, that the most perfect knowledge, thus the purely objective comprehension of the world, *i.e.*, the comprehension of genius, is conditioned by a silence of the will so profound that while it lasts even the individuality vanishes from consciousness and the man remains *as the pure subject of knowing*, which is the correlative of the *Idea*.

The disturbing influence of the will upon the intellect, which is proved by all these phenomena, and, on the other hand, the weakness and frailty of the latter, on account of which it is incapable of working rightly whenever the will is in any way moved, gives us then another proof that the will is the radical part of our nature, and acts with original power, while the intellect, as adventitious and in many ways conditioned, can only act in a subordinate and conditional manner.

There is no direct disturbance of the will by the intellect corresponding to the disturbance and clouding of knowledge by the will that has been shown. Indeed we cannot well conceive such a thing. No one will wish to construe as such the fact that motives wrongly taken up lead the will astray, for this is a fault of the intellect in its own function, which is committed quite within its own province, and the influence of which upon the will is entirely indirect. It would be plausible to attribute *irresolution* to this, for in its case, through the conflict of the motives which the intellect presents to the will, the latter is brought to a standstill, thus is hindered. But when we consider it more closely, it becomes very clear that the cause of this hindrance does not lie in the activity of the *intellect* as such, but entirely in *external objects* which are brought about by it, for in this case they stand in precisely such a relation to the will, which is here interested, that they draw it with nearly equal strength in different directions. This real cause merely acts *through* the intellect as the medium of motives, though certainly under the assumption that it is keen enough to comprehend the objects in their manifold relations. Irresolution, as a trait of character, is just as much conditioned by qualities of the will as of the intellect. It is certainly not peculiar to exceedingly limited minds, for their weak understanding does not allow them to discover such manifold qualities and relations in things, and moreover is so little fitted for the exertion of reflection and pondering these, and then the probable consequences of each step, that they rather decide at once according to the first impression, or according to some simple rule of conduct. The converse of this occurs in the case of persons of considerable understanding. Therefore, whenever such persons also possess a tender care for their own well-being, *i.e.*, a very sensitive egoism, which constantly desires to come off well and always to be safe, this introduces a certain anxiety at every step, and thereby irresolution. This quality therefore indicates throughout not a want of understanding but a want of courage. Yet very eminent minds survey the relations and their probable developments

with such rapidity and certainty, that if they are only supported by some courage they thereby acquire that quick decision and resolution that fits them to play an important part in the affairs of the world, if time and circumstances afford them the opportunity.

The only decided, direct restriction and disturbance which the will can suffer from the intellect as such may indeed be the quite exceptional one, which is the consequence of an abnormally preponderating development of the intellect, thus of that high endowment which has been defined as genius. This is decidedly a hindrance to the energy of the character, and consequently to the power of action. Hence it is not the really great minds that make historical characters, because they are capable of bridling and ruling the mass of men and carrying out the affairs of the world; but for this persons of much less capacity of mind are qualified when they have great firmness, decision, and persistency of will, such as is quite inconsistent with very high intelligence. Accordingly, where this very high intelligence exists we actually have a case in which the intellect directly restricts the will.

6. In opposition to the hindrances and restrictions which it has been shown the intellect suffers from the will, I wish now to show, in a few examples, how, conversely, the functions of the intellect are sometimes aided and heightened by the incitement and spur of the will; so that in this also we may recognise the primary nature of the one and the secondary nature of the other, and it may become clear that the intellect stands to the will in the relation of a tool.

A motive which affects us strongly, such as a yearning desire or a pressing need, sometimes raises the intellect to a degree of which we had not previously believed it capable. Difficult circumstances, which impose upon us the necessity of certain achievements, develop entirely new talents in us, the germs of which were hidden from us, and for which we did not credit ourselves with any capacity. The understanding of the stupidest man becomes keen when objects are in question that closely concern his wishes; he now observes, weighs, and distinguishes with the greatest delicacy even the smallest circumstances that have reference to his wishes or fears. This has much to do with the cunning of half-witted persons, which is often remarked with surprise. On this account Isaiah rightly says, *vexatio dat intellectum*, which is therefore also used as a proverb. Akin to it is the German proverb, “*Die Noth ist die Mutter der Künste*” (“Necessity is the mother of the arts”); when, however, the fine arts are to be excepted,

because the heart of every one of their works, that is, the conception, must proceed from a perfectly will-less, and only thereby purely objective, perception, if they are to be genuine. Even the understanding of the brutes is increased considerably by necessity, so that in cases of difficulty they accomplish things at which we are astonished. For example, they almost all calculate that it is safer not to run away when they believe they are not seen; therefore the hare lies still in the furrow of the field and lets the sportsman pass close to it; insects, when they cannot escape, pretend to be dead, &c. We may obtain a fuller knowledge of this influence from the special history of the self-education of the wolf, under the spur of the great difficulty of its position in civilised Europe; it is to be found in the second letter of Leroy's excellent book, "*Lettres sur l'intelligence et la perfectibilité des animaux*." Immediately afterwards, in the third letter, there follows the high school of the fox, which in an equally difficult position has far less physical strength. In its case, however, this is made up for by great understanding; yet only through the constant struggle with want on the one hand and danger on the other, thus under the spur of the will, does it attain that high degree of cunning which distinguishes it especially in old age. In all these enhancements of the intellect the will plays the part of a rider who with the spur urges the horse beyond the natural measure of its strength.

In the same way the memory is enhanced through the pressure of the will. Even if it is otherwise weak, it preserves perfectly what has value for the ruling passion. The lover forgets no opportunity favourable to him, the ambitious man forgets no circumstance that can forward his plans, the avaricious man never forgets the loss he has suffered, the proud man never forgets an injury to his honour, the vain man remembers every word of praise and the most trifling distinction that falls to his lot. And this also extends to the brutes: the horse stops at the inn where once long ago it was fed; dogs have an excellent memory for all occasions, times, and places that have afforded them choice morsels; and foxes for the different hiding-places in which they have stored their plunder.

Self-consideration affords opportunity for finer observations in this regard. Sometimes, through an interruption, it has entirely escaped me what I have just been thinking about, or even what news I have just heard. Now if the matter had in any way even the most distant personal interest, the after-feeling of the impression which it made upon the *will* has remained. I am still quite conscious how far it affected me agreeably or disagreeably, and

also of the special manner in which this happened, whether, even in the slightest degree, it vexed me, or made me anxious, or irritated me, or depressed me, or produced the opposite of these affections. Thus the mere relation of the thing to my will is retained in the memory after the thing itself has vanished, and this often becomes the clue to lead us back to the thing itself. The sight of a man sometimes affects us in an analogous manner, for we remember merely in general that we have had something to do with him, yet without knowing where, when, or what it was, or who he is. But the sight of him still recalls pretty accurately the feeling which our dealings with him excited in us, whether it was agreeable or disagreeable, and also in what degree and in what way. Thus our memory has preserved only the response of the will, and not that which called it forth. We might call what lies at the foundation of this process the memory of the heart; it is much more intimate than that of the head. Yet at bottom the connection of the two is so far-reaching that if we reflect deeply upon the matter we will arrive at the conclusion that memory in general requires the support of a will as a connecting point, or rather as a thread upon which the memories can range themselves, and which holds them firmly together, or that the will is, as it were, the ground to which the individual memories cleave, and without which they could not last; and that therefore in a pure intelligence, *i.e.*, in a merely knowing and absolutely will-less being, a memory cannot well be conceived. Accordingly the improvement of the memory under the spur of the ruling passion, which has been shown above, is only the higher degree of that which takes place in all retention and recollection; for its basis and condition is always the will. Thus in all this also it becomes clear how very much more essential to us the will is than the intellect. The following facts may also serve to confirm this.

The intellect often obeys the will; for example, if we wish to remember something, and after some effort succeed; so also if we wish now to ponder something carefully and deliberately, and in many such cases. Sometimes, again, the intellect refuses to obey the will; for example, if we try in vain to fix our minds upon something, or if we call in vain upon the memory for something that was intrusted to it. The anger of the will against the intellect on such occasions makes its relation to it and the difference of the two very plain. Indeed the intellect, vexed by this anger, sometimes officiously brings what was asked of it hours afterwards, or even the following morning, quite unexpectedly and unseasonably. On the other hand, the will never really

obeys the intellect; but the latter is only the ministerial council of that sovereign; it presents all kinds of things to the will, which then selects what is in conformity with its nature, though in doing so it determines itself with necessity, because this nature is unchangeable and the motives now lie before it. Hence no system of ethics is possible which moulds and improves the will itself. For all teaching only affects *knowledge*, and knowledge never determines the will itself, *i.e.*, the *fundamental character* of willing, but only its application to the circumstances present. Rectified knowledge can only modify conduct so far as it proves more exactly and judges more correctly what objects of the will's choice are within its reach; so that the will now measures its relation to things more correctly, sees more clearly what it desires, and consequently is less subject to error in its choice. But over the will itself, over the main tendency or fundamental maxim of it, the intellect has no power. To believe that knowledge really and fundamentally determines the will is like believing that the lantern which a man carries by night is the *primum mobile* of his steps. Whoever, taught by experience or the admonitions of others, knows and laments a fundamental fault of his character, firmly and honestly forms the intention to reform and give it up; but in spite of this, on the first opportunity, the fault receives free course. New repentance, new intentions, new transgressions. When this has been gone through several times he becomes conscious that he cannot improve himself, that the fault lies in his nature and personality, indeed is one with this. Now he will blame and curse his nature and personality, will have a painful feeling, which may rise to anguish of consciousness, but to change these he is not able. Here we see that which condemns and that which is condemned distinctly separate: we see the former as a merely theoretical faculty, picturing and presenting the praiseworthy, and therefore desirable, course of life, but the other as something real and unchangeably present, going quite a different way in spite of the former: and then again the first remaining behind with impotent lamentations over the nature of the other, with which, through this very distress, it again identifies itself. Will and intellect here separate very distinctly. But here the will shows itself as the stronger, the invincible, unchangeable, primitive, and at the same time as the essential thing in question, for the intellect deplores its errors, and finds no comfort in the correctness of the *knowledge*, as its own function. Thus the intellect shows itself entirely secondary, as the spectator of the deeds of another, which it accompanies with impotent praise and blame, and also as

determinable from without, because it learns from experience, weighs and alters its precepts. Special illustrations of this subject will be found in the "*Parerga*," vol. ii. § 118 (second ed., § 119.) Accordingly, a comparison of our manner of thinking at different periods of our life will present a strange mixture of permanence and changeableness. On the one hand, the moral tendency of the man in his prime and the old man is still the same as was that of the boy; on the other hand, much has become so strange to him that he no longer knows himself, and wonders how he ever could have done or said this and that. In the first half of life to-day for the most part laughs at yesterday, indeed looks down on it with contempt; in the second half, on the contrary, it more and more looks back at it with envy. But on closer examination it will be found that the changeable element was the *intellect*, with its functions of insight and knowledge, which, daily appropriating new material from without, presents a constantly changing system of thought, while, besides this, it itself rises and sinks with the growth and decay of the organism. The will, on the contrary, the basis of this, thus the inclinations, passions, and emotions, the character, shows itself as what is unalterable in consciousness. Yet we have to take account of the modifications that depend upon physical capacities for enjoyment, and hence upon age. Thus, for example, the eagerness for sensuous pleasure will show itself in childhood as a love of dainties, in youth and manhood as the tendency to sensuality, and in old age again as a love of dainties.

7. If, as is generally assumed, the will proceeded from knowledge, as its result or product, then where there is much will there would necessarily also be much knowledge, insight, and understanding. This, however, is absolutely not the case; rather, we find in many men a strong, *i.e.*, decided, resolute, persistent, unbending, wayward, and vehement will, combined with a very weak and incapable understanding, so that every one who has to do with them is thrown into despair, for their will remains inaccessible to all reasons and ideas, and is not to be got at, so that it is hidden, as it were, in a sack, out of which it wills blindly. Brutes have often violent, often stubborn wills, but yet very little understanding. Finally, plants only will without any knowledge at all.

If willing sprang merely from knowledge, our *anger* would necessarily be in every case exactly proportionate to the occasion, or at least to our relation to it, for it would be nothing more than the result of the present knowledge. This, however, is rarely the case; rather, anger generally goes

far beyond the occasion. Our fury and rage, the *furor brevis*, often upon small occasions, and without error regarding them, is like the raging of an evil spirit which, having been shut up, only waits its opportunity to dare to break loose, and now rejoices that it has found it. This could not be the case if the foundation of our nature were a *knower*, and willing were merely a result of *knowledge*; for how came there into the result what did not lie in the elements? The conclusion cannot contain more than the premisses. Thus here also the will shows itself as of a nature quite different from knowledge, which only serves it for communication with the external world, but then the will follows the laws of its own nature without taking from the intellect anything but the occasion.

The intellect, as the mere tool of the will, is as different from it as the hammer from the smith. So long as in a conversation the intellect alone is active it remains *cold*. It is almost as if the man himself were not present. Moreover, he cannot then, properly speaking, compromise himself, but at the most can make himself ridiculous. Only when the will comes into play is the man really present: now he becomes *warm*, nay, it often happens, *hot*. It is always the will to which we ascribe the warmth of life; on the other hand, we say the *cold* understanding, or to investigate a thing *coolly*, *i.e.*, to think without being influenced by the will. If we attempt to reverse the relation, and to regard the will as the tool of the intellect, it is as if we made the smith the tool of the hammer.

Nothing is more provoking, when we are arguing against a man with reasons and explanations, and taking all pains to convince him, under the impression that we have only to do with his *understanding*, than to discover at last that he *will* not understand; that thus we had to do with his *will*, which shuts itself up against the truth and brings into the field wilful misunderstandings, chicaneries, and sophisms in order to intrench itself behind its understanding and its pretended want of insight. Then he is certainly not to be got at, for reasons and proofs applied against the will are like the blows of a phantom produced by mirrors against a solid body. Hence the saying so often repeated, "*Stat pro ratione voluntas.*" Sufficient evidence of what has been said is afforded by ordinary life. But unfortunately proofs of it are also to be found on the path of the sciences. The recognition of the most important truths, of the rarest achievements, will be looked for in vain from those who have an interest in preventing them from being accepted, an interest which either springs from the fact

that such truths contradict what they themselves daily teach, or else from this, that they dare not make use of them and teach them; or if all this be not the case they will not accept them, because the watchword of mediocrity will always be, *Si quelqu'un excelle parmi nous, qu'il aille exceller ailleurs*, as Helvetius has admirably rendered the saying of the Ephesian in the fifth book of Cicero's "*Tusculanæ*" (c. 36), or as a saying of the Abyssinian Fit Arari puts it, "Among quartzes adamant is outlawed." Thus whoever expects from this always numerous band a just estimation of what he has done will find himself very much deceived, and perhaps for a while he will not be able to understand their behaviour, till at last he finds out that while he applied himself to *knowledge* he had to do with the *will*, thus is precisely in the position described above, nay, is really like a man who brings his case before a court the judges of which have all been bribed. Yet in particular cases he will receive the fullest proof that their will and not their insight opposed him, when one or other of them makes up his mind to plagiarism. Then he will see with astonishment what good judges they are, what correct perception of the merit of others they have, and how well they know how to find out the best, like the sparrows, who never miss the ripest cherries.

The counterpart of the victorious resistance of the will to knowledge here set forth appears if in expounding our reasons and proofs we have the will of those addressed with us. Then all are at once convinced, all arguments are telling, and the matter is at once clear as the day. This is well known to popular speakers. In the one case, as in the other, the will shows itself as that which has original power, against which the intellect can do nothing.

8. But now we shall take into consideration the individual qualities, thus excellences and faults of the will and character on the one hand, and of the intellect on the other, in order to make clear, in their relation to each other, and their relative worth, the complete difference of the two fundamental faculties. History and experience teach that the two appear quite independently of each other. That the greatest excellence of mind will not easily be found combined with equal excellence of character is sufficiently explained by the extraordinary rarity of both, while their opposites are everywhere the order of the day; hence we also daily find the latter in union. However, we never infer a good will from a superior mind, nor the latter from the former, nor the opposite from the opposite, but every unprejudiced person accepts them as perfectly distinct qualities, the presence of which each for itself has to be learned from experience. Great

narrowness of mind may coexist with great goodness of heart, and I do not believe Balthazar Gracian was right in saying (*Discreto*, p. 406), "*No ay simple, que no sea malicioso*" ("There is no simpleton who would not be malicious"), though he has the Spanish proverb in his favour, "*Nunca la necedad anduvo sin malicia*" ("Stupidity is never without malice"). Yet it may be that many stupid persons become malicious for the same reason as many hunchbacks, from bitterness on account of the neglect they have suffered from nature, and because they think they can occasionally make up for what they lack in understanding through malicious cunning, seeking in this a brief triumph. From this, by the way, it is also comprehensible why almost every one easily becomes malicious in the presence of a very superior mind. On the other hand, again, stupid people have very often the reputation of special good-heartedness, which yet so seldom proves to be the case that I could not help wondering how they had gained it, till I was able to flatter myself that I had found the key to it in what follows. Moved by a secret inclination, every one likes best to choose for his more intimate intercourse some one to whom he is a little superior in understanding, for only in this case does he find himself at his ease, because, according to Hobbes, "*Omnis animi voluptas, omnisgue alacritas in eo sita est, quod quis habeat, quibuscum conferens se, possit magnifice sentire de se ipso*" (*De Cive*, i. 5). For the same reason every one avoids him who is superior to himself; wherefore Lichtenberg quite rightly observes: "To certain men a man of mind is a more odious production than the most pronounced rogue." And similarly Helvetius says: "*Les gens médiocres ont un instinct sûr et prompt, pour connaître et fuir les gens d'esprit.*" And Dr. Johnson assures us that "there is nothing by which a man exasperates most people more than by displaying a superior ability of brilliancy in conversation. They seem pleased at the time, but their envy makes them curse him in their hearts" (Boswell; aet. anno 74). In order to bring this truth, so universal and so carefully concealed, more relentlessly to light, I add the expression of it by Merck, the celebrated friend of Goethe's youth, from his story "*Lindor:*" "He possessed talents which were given him by nature and acquired by himself through learning; and thus it happened that in most society he left the worthy members of it far behind." If, in the moment of delight at the sight of an extraordinary man, the public swallows these superiorities also, without actually at once putting a bad construction upon them, yet a certain impression of this phenomenon remains behind, which, if it is often

repeated, may on serious occasions have disagreeable future consequences for him who is guilty of it. Without any one consciously noting that on this occasion he was insulted, no one is sorry to place himself tacitly in the way of the advancement of this man. Thus on this account great mental superiority isolates more than anything else, and makes one, at least silently, hated. Now it is the opposite of this that makes stupid people so generally liked; especially since many can only find in them what, according to the law of their nature referred to above, they must seek. Yet this the true reason of such an inclination no one will confess to himself, still less to others; and therefore, as a plausible pretext for it, will impute to those he has selected a special goodness of heart, which, as we have said, is in reality only very rarely and accidentally found in combination with mental incapacity. Want of understanding is accordingly by no means favourable or akin to goodness of character. But, on the other hand, it cannot be asserted that great understanding is so; nay, rather, no scoundrel has in general been without it. Indeed even the highest intellectual eminence can coexist with the worst moral depravity. An example of this is afforded by Bacon of Verulam: "Ungrateful, filled with the lust of power, wicked and base, he at last went so far that, as Lord Chancellor and the highest judge of the realm, he frequently allowed himself to be bribed in civil actions. Impeached before his peers, he confessed himself guilty, was expelled by them from the House of Lords, and condemned to a fine of forty thousand pounds and imprisonment in the Tower" (see the review of the latest edition of Bacon's Works in the *Edinburgh Review*, August 1837). Hence also Pope called him "the wisest, brightest, meanest of mankind" ("Essay on Man," iv. 282). A similar example is afforded by the historian Guicciardini, of whom Rosini says in the *Notizie Storiche*, drawn from good contemporary sources, which is given in his historical romance "*Luisa Strozzi*:" "*Da coloro, che pongono l'ingegno e il sapere al di sopra di tutte le umane qualità, questo uomo sarà riguardato come fra i più grandi del suo secolo: ma da quelli, che reputano la virtù dovere andare innanzi a tutto, non potra esecrarsi abbastanza la sua memoria. Esso fu il più crudele fra i cittadini a perseguitare, uccidere e confinare*," &c.[32]

If now it is said of one man, "He has a good heart, though a bad head," but of another, "He has a very good head, yet a bad heart," every one feels that in the first case the praise far outweighs the blame — in the other case the reverse. Answering to this, we see that if some one has done a bad deed

his friends and he himself try to remove the guilt from the *will* to the *intellect*, and to give out that faults of the heart were faults of the head; roguish tricks they will call *errors*, will say they were merely want of understanding, want of reflection, light-mindedness, folly; nay, if need be, they will plead a paroxysm, momentary mental aberration, and if a heavy crime is in question, even madness, only in order to free the *will* from the guilt. And in the same way, we ourselves, if we have caused a misfortune or injury, will before others and ourselves willingly impeach our *stultitia*, simply in order to escape the reproach of *malitia*. In the same way, in the case of the equally unjust decision of the judge, the difference, whether he has erred or been bribed, is so infinitely great. All this sufficiently proves that the *will* alone is the real and essential, the kernel of the man, and the *intellect* is merely its tool, which may be constantly faulty without the will being concerned. The accusation of want of understanding is, at the moral judgment-seat, no accusation at all; on the contrary, it even gives privileges. And so also, before the courts of the world, it is everywhere sufficient to deliver a criminal from all punishment that his guilt should be transferred from his will to his intellect, by proving either unavoidable error or mental derangement, for then it is of no more consequence than if hand or foot had slipped against the will. I have fully discussed this in the appendix, "*Ueber die Intellektuelle Freiheit*," to my prize essay on the freedom of the will, to which I refer to avoid repetition.

Everywhere those who are responsible for any piece of work appeal, in the event of its turning out unsatisfactorily, to their good intentions, of which there was no lack. Hereby they believe that they secure the essential, that for which they are properly answerable, and their true self; the inadequacy of their faculties, on the other hand, they regard as the want of a suitable tool.

If a man is *stupid*, we excuse him by saying that he cannot help it; but if we were to excuse a *bad* man on the same grounds we would be laughed at. And yet the one, like the other, is innate. This proves that the will is the man proper, the intellect merely its tool.

Thus it is always only our *willing* that is regarded as depending upon ourselves, *i.e.*, as the expression of our true nature, and for which we are therefore made responsible. Therefore it is absurd and unjust if we are taken to task for our beliefs, thus for our knowledge: for we are obliged to regard

this as something which, although it changes in us, is as little in our power as the events of the external world. And here, also, it is clear that the *will* alone is the inner and true nature of man; the *intellect*, on the contrary, with its operations, which go on as regularly as the external world, stands to the will in the relation of something external to it, a mere tool.

High mental capacities have always been regarded as the gift of nature or the gods; and on that account they have been called *Gaben*, *Begabung*, *ingenii dotes*, gifts (a man highly gifted), regarding them as something different from the man himself, something that has fallen to his lot through favour. No one, on the contrary, has ever taken this view of moral excellences, although they also are innate; they have rather always been regarded as something proceeding from the man himself, essentially belonging to him, nay, constituting his very self. But it follows now from this that the will is the true nature of man; the intellect, on the other hand, is secondary, a tool, a gift.

Answering to this, all religions promise a reward beyond life, in eternity, for excellences of the *will* or heart, but none for excellences of the head or understanding. Virtue expects its reward in that world; prudence hopes for it in this; genius, again, neither in this world nor in that; it is its own reward. Accordingly the will is the eternal part, the intellect the temporal.

Connection, communion, intercourse among men is based, as a rule, upon relations which concern the *will*, not upon such as concern the *intellect*. The first kind of communion may be called the *material*, the other the *formal*. Of the former kind are the bonds of family and relationship, and further, all connections that rest upon any common aim or interest, such as that of trade or profession, of the corporation, the party, the faction, &c. In these it merely amounts to a question of views, of aims; along with which there may be the greatest diversity of intellectual capacity and culture. Therefore not only can any one live in peace and unity with any one else, but can act with him and be allied to him for the common good of both. Marriage also is a bond of the heart, not of the head. It is different, however, with merely formal communion, which aims only at an exchange of thought; this demands a certain equality of intellectual capacity and culture. Great differences in this respect place between man and man an impassable gulf: such lies, for example, between a man of great mind and a fool, between a scholar and a peasant, between a courtier and a sailor. Natures as heterogeneous as this have therefore trouble in making themselves

intelligible so long as it is a question of exchanging thoughts, ideas, and views. Nevertheless close *material* friendship may exist between them, and they may be faithful allies, conspirators, or men under mutual pledges. For in all that concerns the will alone, which includes friendship, enmity, honesty, fidelity, falseness, and treachery, they are perfectly homogeneous, formed of the same clay, and neither mind nor culture make any difference here; indeed here the ignorant man often shames the scholar, the sailor the courtier. For at the different grades of culture there are the same virtues and vices, emotions and passions; and although somewhat modified in their expression, they very soon mutually recognise each other even in the most heterogeneous individuals, upon which the similarly disposed agree and the opposed are at enmity.

Brilliant qualities of mind win admiration, but never affection; this is reserved for the moral, the qualities of the character. Every one will choose as his friend the honest, the good-natured, and even the agreeable, complaisant man, who easily concurs, rather than the merely able man. Indeed many will be preferred to the latter, on account of insignificant, accidental, outward qualities which just suit the inclination of another. Only the man who has much mind himself will wish able men for his society; his friendship, on the other hand, he will bestow with reference to moral qualities; for upon this depends his really high appreciation of a man in whom a single good trait of character conceals and expiates great want of understanding. The known goodness of a character makes us patient and yielding towards weaknesses of understanding, as also towards the dulness and childishness of age. A distinctly noble character along with the entire absence of intellectual excellence and culture presents itself as lacking nothing; while, on the contrary, even the greatest mind, if affected with important moral faults, will always appear blamable. For as torches and fireworks become pale and insignificant in the presence of the sun, so intellect, nay, genius, and also beauty, are outshone and eclipsed by the goodness of the heart. When this appears in a high degree it can make up for the want of those qualities to such an extent that one is ashamed of having missed them. Even the most limited understanding, and also grotesque ugliness, whenever extraordinary goodness of heart declares itself as accompanying them, become as it were transfigured, outshone by a beauty of a higher kind, for now a wisdom speaks out of them before which all other wisdom must be dumb. For goodness of heart is a transcendent

quality; it belongs to an order of things that reaches beyond this life, and is incommensurable with any other perfection. When it is present in a high degree it makes the heart so large that it embraces the world, so that now everything lies within it, no longer without; for it identifies all natures with its own. It then extends to others also that boundless indulgence which otherwise each one only bestows on himself. Such a man is incapable of becoming angry; even if the malicious mockery and sneers of others have drawn attention to his own intellectual or physical faults, he only reproaches himself in his heart for having been the occasion of such expressions, and therefore, without doing violence to his own feelings, proceeds to treat those persons in the kindest manner, confidently hoping that they will turn from their error with regard to him, and recognise themselves in him also. What is wit and genius against this? — what is Bacon of Verulam?

Our estimation of our own selves leads to the same result as we have here obtained by considering our estimation of others. How different is the self-satisfaction which we experience in a moral regard from that which we experience in an intellectual regard! The former arises when, looking back on our conduct, we see that with great sacrifices we have practised fidelity and honesty, that we have helped many, forgiven many, have behaved better to others than they have behaved to us; so that we can say with King Lear, "I am a man more sinned against than sinning;" and to its fullest extent if perhaps some noble deed shines in our memory. A deep seriousness will accompany the still peace which such a review affords us; and if we see that others are inferior to us here, this will not cause us any joy, but we will rather deplore it, and sincerely wish that they were as we are. How entirely differently does the knowledge of our intellectual superiority affect us! Its ground bass is really the saying of Hobbes quoted above: *Omnis animi voluptas, omnisque alacritas in eo sita est, quad quis habeat, quibuscum conferens se, possit magnifice sentire de se ipso.* Arrogant, triumphant vanity, proud, contemptuous looking down on others, inordinate delight in the consciousness of decided and considerable superiority, akin to pride of physical advantages, — that is the result here. This opposition between the two kinds of self-satisfaction shows that the one concerns our true inner and eternal nature, the other a more external, merely temporal, and indeed scarcely more than a mere physical excellence. The *intellect* is in fact

simply the function of the brain; the *will*, on the contrary, is that whose function is the whole man, according to his being and nature.

If, looking without us, we reflect that ὁ βιος βραχυς, ἡ δε τεχνη μακρα (*vita brevis, ars longa*), and consider how the greatest and most beautiful minds, often when they have scarcely reached the summit of their power, and the greatest scholars, when they have only just attained to a thorough knowledge of their science, are snatched away by death, we are confirmed in this, that the meaning and end of life is not intellectual but moral.

The complete difference between the mental and moral qualities displays itself lastly in the fact that the intellect suffers very important changes through time, while the will and character remain untouched by it. The new-born child has as yet no use of its understanding, but obtains it within the first two months to the extent of perception and apprehension of the things in the external world — a process which I have described more fully in my essay, "*Ueber das Sehn und die Farben*," p. 10 of the second (and third) edition. The growth of reason to the point of speech, and thereby of thought, follows this first and most important step much more slowly, generally only in the third year; yet the early childhood remains hopelessly abandoned to silliness and folly, primarily because the brain still lacks physical completeness, which, both as regards its size and texture, it only attains in the seventh year. But then for its energetic activity there is still wanting the antagonism of the genital system; it therefore only begins with puberty. Through this, however, the intellect has only attained to the *capacity* for its psychical improvement; this itself can only be won by practice, experience, and instruction. Thus as soon as the mind has escaped from the folly of childhood it falls into the snares of innumerable errors, prejudices, and chimeras, sometimes of the absurdest and crudest kind, which it obstinately sticks to, till experience gradually removes them, and many of them also are insensibly lost. All this takes many years to happen, so that one grants it majority indeed soon after the twentieth year, yet has placed full maturity, years of discretion, not before the fortieth year. But while this psychical education, resting upon help from without, is still in process of growth, the inner *physical* energy of the brain already begins to sink again. This has reached its real culminating point about the thirtieth year, on account of its dependence upon the pressure of blood and the effect of the pulsation upon the brain, and through this again upon the predominance of the arterial over the venous system, and the fresh tenderness of the brain fibre, and also on

account of the energy of the genital system. After the thirty-fifth year a slight diminution of the physical energy of the brain becomes noticeable, which, through the gradually approaching predominance of the venous over the arterial system, and also through the increasing firmer and drier consistency of the brain fibre, more and more takes place, and would be much more observable if it were not that, on the other hand, the psychical perfecting, through exercise, experience, increase of knowledge, and acquired skill in the use of it, counteracts it — an antagonism which fortunately lasts to an advanced age, for the brain becomes more and more like a worn-out instrument. But yet the diminution of the original energy of the intellect, resting entirely upon organic conditions, continues, slowly indeed, but unceasingly: the faculty of original conception, the imagination, the plastic power, the memory, become noticeably weaker; and so it goes on step by step downwards into old age, garrulous, without memory, half-unconscious, and ultimately quite childish.

The will, on the contrary, is not affected by all this becoming, this change and vicissitude, but is from beginning to end unalterably the same. *Willing* does not require to be learned like *knowing*, but succeeds perfectly at once. The new-born child makes violent movements, rages, and cries; it wills in the most vehement manner, though it does not yet know what it wills. For the medium of motives, the intellect, is not yet fully developed. The will is in darkness concerning the external world, in which its objects lie, and now rages like a prisoner against the walls and bars of his dungeon. But little by little it becomes light: at once the fundamental traits of universal human willing, and, at the same time, the individual modification of it here present, announce themselves. The already appearing character shows itself indeed at first in weak and uncertain outline, on account of the defective service of the intellect, which has to present it with motives; but to the attentive observer it soon declares its complete presence, and in a short time it becomes unmistakable. The characteristics appear which last through the whole of life; the principal tendencies of the will, the easily excited emotions, the ruling passion, declare themselves. Therefore the events at school stand to those of the future life for the most part as the dumb-show in "Hamlet" that precedes the play to be given at the court, and foretells its content in the form of pantomime, stands to the play itself. But it is by no means possible to prognosticate in the same way the future intellectual capacities of the man from those shown in the boy; rather as a rule the

ingenia prœcocia, prodigies, turn out block-heads; genius, on the contrary, is often in childhood of slow conception, and comprehends with difficulty, just because it comprehends deeply. This is how it is that every one relates laughing and without reserve the follies and stupidities of his childhood. For example, Goethe, how he threw all the kitchen crockery out of the window (*Dichtung und Wahrheit*, vol. i. p. 7); for we know that all this only concerns what changes. On the other hand, a prudent man will not favour us with the bad features, the malicious or deceitful actions, of his youth, for he feels that they also bear witness to his present character. I have been told that when Gall, the phrenologist and investigator of man, had to put himself into connection with a man as yet unknown to him, he used to get him to speak about his youthful years and actions, in order, if possible, to gather from these the distinctive traits of his character; because this must still be the same now. This is the reason why we are indifferent to the follies and want of understanding of our youthful years, and even look back on them with smiling satisfaction, while the bad features of character even of that time, the ill-natured actions and the misdeeds then committed exist even in old age as inextinguishable reproaches, and trouble our consciences. Now, just as the character appears complete, so it remains unaltered to old age. The advance of age, which gradually consumes the intellectual powers, leaves the moral qualities untouched. The goodness of the heart still makes the old man honoured and loved when his head already shows the weaknesses which are the commencement of second childhood. Gentleness, patience, honesty, veracity, disinterestedness, philanthropy, &c., remain through the whole life, and are not lost through the weaknesses of old age; in every clear moment of the worn-out old man they come forth undiminished, like the sun from the winter clouds. And, on the other hand, malice, spite, avarice, hard-heartedness, infidelity, egoism, and baseness of every kind also remain undiminished to our latest years. We would not believe but would laugh at any one who said to us, "In former years I was a malicious rogue, but now I am an honest and noble-minded man." Therefore Sir Walter Scott, in the "Fortunes of Nigel," has shown very beautifully, in the case of the old usurer, how burning avarice, egoism, and injustice are still in their full strength, like a poisonous plant in autumn, when the intellect has already become childish. The only alterations that take place in our inclinations are those which result directly from the decrease of our physical strength, and with it of our capacities for

enjoyment. Thus voluptuousness will make way for intemperance, the love of splendour for avarice, and vanity for ambition; just like the man who before he has a beard will wear a false one, and later, when his own beard has become grey, will dye it brown. Thus while all organic forces, muscular power, the senses, the memory, wit, understanding, genius, wear themselves out, and in old age become dull, the will alone remains undecayed and unaltered: the strength and the tendency of willing remains the same. Indeed in many points the will shows itself still more decided in age: thus, in the clinging to life, which, it is well known, increases; also in the firmness and persistency with regard to what it has once embraced, in obstinacy; which is explicable from the fact that the susceptibility of the intellect for other impressions, and thereby the movement of the will by motives streaming in upon it, has diminished. Hence the implacable nature of the anger and hate of old persons —

"The young man's wrath is like light straw on fire,
But like red-hot steel is the old man's ire."
— *Old Ballad.*

From all these considerations it becomes unmistakable to the more penetrating glance that, while the *intellect* has to run through a long series of gradual developments, but then, like everything physical, must encounter decay, the *will* takes no part in this, except so far as it has to contend at first with the imperfection of its tool, the intellect, and, again, at last with its worn-out condition, but itself appears perfect and remains unchanged, not subject to the laws of time and of becoming and passing away in it. Thus in this way it makes itself known as that which is metaphysical, not itself belonging to the phenomenal world.

9. The universally used and generally very well understood expressions *heart* and *head* have sprung from a true feeling of the fundamental distinction here in question; therefore they are also apt and significant, and occur in all languages. *Nec cor nec caput habet*, says Seneca of the Emperor Claudius (*Ludus de morte Claudii Cæsaris*, c. 8). The heart, this *primum mobile* of the animal life, has with perfect justice been chosen as the symbol, nay, the synonym, of the *will*, as the primary kernel of our phenomenon, and denotes this in opposition to the intellect, which is exactly identical with the head. All that, in the widest sense, is matter of the will, as wish, passion, joy, grief, goodness, wickedness, also what we are wont to understand under "Gemüth," and what Homer expresses through

φιλον ἤτορ, is attributed to the *heart*. Accordingly we say: He has a bad heart; — his heart is in the thing; — it comes from his heart; — it cut him to the heart; — it breaks his heart; — his heart bleeds; — the heart leaps for joy; — who can see the heart of man? — it is heart-rending, heart-crushing, heart-breaking, heart-inspiring, heart-touching; — he is good-hearted, hard-hearted, heartless, stout-hearted, faint-hearted, &c. &c. Quite specially, however, love affairs are called affairs of the heart, *affaires de cœur*; because the sexual impulse is the focus of the will, and the selection with reference to it constitutes the chief concern of natural, human volition, the ground of which I shall show in a full chapter supplementary to the fourth book. Byron in "Don Juan," c. xi. v. 34, is satirical about love being to women an affair of the head instead of an affair of the heart. On the other hand, the *head* denotes everything that is matter of *knowledge*. Hence a man of head, a good head, a fine head, a bad head, to lose one's head, to keep one's head uppermost, &c. Heart and head signifies the whole man. But the head is always the second, the derived; for it is not the centre but the highest efflorescence of the body. When a hero dies his heart is embalmed, not his brain; on the other hand, we like to preserve the skull of the poet, the artist, and the philosopher. So Raphael's skull was preserved in the Academia di S. Luca at Rome, though it has lately been proved not to be genuine; in Stockholm in 1820 the skull of Descartes was sold by auction.[33]

A true feeling of the real relation between will, intellect, and life is also expressed in the Latin language. The intellect is *mens*, νους; the will again is *animus*, which comes from *anima*, and this from ανεμων. *Anima* is the life itself, the breath, ψυχη; but *animus* is the living principle, and also the will, the subject of inclinations, intentions, passions, emotions; hence also *est mihi animus*, — *fert animus*, — for "I have a desire to," also *animi causa*, &c.; it is the Greek θυμος, the German "Gemüth," thus the heart but not the head. *Animi perturbatio* is an emotion; *mentis perturbatio* would signify insanity. The predicate *immortalis* is attributed to *animus*, not to *mens*. All this is the rule gathered from the great majority of passages; though in the case of conceptions so nearly related it cannot but be that the words are sometimes interchanged. Under ψυχη the Greeks appear primarily and originally to have understood the vital force, the living principle, whereby at once arose the dim sense that it must be something

metaphysical, which consequently would not be reached by death. Among other proofs of this are the investigations of the relation between νους and ψυχη preserved by Stobæus (*Ecl.*, Lib. i. c. 51, § 7, 8).

10. Upon what depends the *identity of the person*? Not upon the matter of the body; it is different after a few years. Not upon its form, which changes as a whole and in all its parts; all but the expression of the glance, by which, therefore, we still know a man even after many years; which proves that in spite of all changes time produces in him something in him remains quite untouched by it. It is just this by which we recognise him even after the longest intervals of time, and find the former man entire. It is the same with ourselves, for, however old we become, we yet feel within that we are entirely the same as we were when we were young, nay, when we were still children. This, which unaltered always remains quite the same, and does not grow old along with us, is really the kernel of our nature, which does not lie in time. It is assumed that the identity of the person rests upon that of consciousness. But by this is understood merely the connected recollection of the course of life; hence it is not sufficient. We certainly know something more of our life than of a novel we have formerly read, yet only very little. The principal events, the interesting scenes, have impressed themselves upon us; in the remainder a thousand events are forgotten for one that has been retained. The older we become the more do things pass by us without leaving any trace. Great age, illness, injury of the brain, madness, may deprive us of memory altogether, but the identity of the person is not thereby lost. It rests upon the identical *will* and the unalterable character of the person. It is it also which makes the expression of the glance unchangeable. In the *heart* is the man, not in the head. It is true that, in consequence of our relation to the external world, we are accustomed to regard as our real self the subject of knowledge, the knowing I, which wearies in the evening, vanishes in sleep, and in the morning shines brighter with renewed strength. This is, however, the mere function of the brain, and not our own self. Our true self, the kernel of our nature, is what is behind that, and really knows nothing but willing and not willing, being content and not content, with all the modifications of this, which are called feelings, emotions, and passions. This is that which produces the other, does not sleep with it when it sleeps, and in the same way when it sinks in death remains uninjured. Everything, on the contrary, that belongs to *knowledge* is exposed to oblivion; even actions of moral significance can sometimes,

after years, be only imperfectly recalled, and we no longer know accurately and in detail how we acted on a critical occasion. But the *character itself*, to which the actions only testify, cannot be forgotten by us; it is now still quite the same as then. The will itself, alone and for itself, is permanent, for it alone is unchangeable, indestructible, not growing old, not physical, but metaphysical, not belonging to the phenomenal appearance, but to that itself which so appears. How the identity of consciousness also, so far as it goes, depends upon it I have shown above in chapter 15, so I need not dwell upon it further here.

11. Aristotle says in passing, in his book on the comparison of the desirable, “To live well is better than to live” (βελτιον του ζῃν το ευ ζῃν, Top. iii. 2). From this we might infer, by double contraposition, not to live is better than to live badly. This is also evident to the intellect; yet the great majority live very badly rather than not at all. This clinging to life cannot therefore have its ground in the *object* of life, since life, as was shown in the fourth book, is really a constant suffering, or at the least, as will be shown further on in the 28th chapter, a business which does not cover its expenses; thus that clinging to life can only be founded in the *subject* of it. But it is not founded in the *intellect*, it is no result of reflection, and in general is not a matter of choice; but this willing of life is something that is taken for granted: it is a *prius* of the intellect itself. We ourselves are the will to live, and therefore we must live, well or ill. Only from the fact that this clinging to a life which is so little worth to them is entirely *a priori* and not a *posteriori* can we explain the excessive fear of death that dwells in every living thing, which Rochefoucauld has expressed in his last reflection, with rare frankness and naïveté, and upon which the effect of all tragedies and heroic actions ultimately rest, for it would be lost if we prized life only according to its objective worth. Upon this inexpressible *horror mortis* is also founded the favourite principle of all ordinary minds, that whosoever takes his own life must be mad; yet not less the astonishment, mingled with a certain admiration, which this action always excites even in thinking minds, because it is so opposed to the nature of all living beings that in a certain sense we are forced to admire him who is able to perform it. For suicide proceeds from a purpose of the intellect, but our will to live is a *prius* of the intellect. Thus this consideration also, which will be fully discussed in chapter 28, confirms the primacy of the will in self-consciousness.

12. On the other hand, nothing proves more clearly the secondary, dependent, conditioned nature of the *intellect* than its periodical intermittance. In deep sleep all knowing and forming of ideas ceases. But the kernel of our nature, the metaphysical part of it which the organic functions necessarily presuppose as their *primum mobile*, must never pause if life is not to cease, and, moreover, as something metaphysical and therefore incorporeal, it requires no rest. Therefore the philosophers who set up a *soul* as this metaphysical kernel, *i.e.*, an originally and essentially *knowing* being, see themselves forced to the assertion that this soul is quite untiring in its perceiving and knowing, therefore continues these even in deep sleep; only that we have no recollection of this when we awake. The falseness of this assertion, however, was easy to see whenever one had rejected that *soul* in consequence of Kant's teaching. For sleep and waking prove to the unprejudiced mind in the clearest manner that knowing is a secondary function and conditioned by the organism, just like any other. Only the *heart* is untiring, because its beating and the circulation of the blood are not directly conditioned by nerves, but are just the original manifestation of the will. Also all other physiological functions governed merely by ganglionic nerves, which have only a very indirect and distant connection with the brain, are carried on during sleep, although the secretions take place more slowly; the beating of the heart itself, on account of its dependence upon respiration, which is conditioned by the cerebral system (*medulla oblongata*), becomes with it a little slower. The stomach is perhaps most active in sleep, which is to be attributed to its special consensus with the now resting brain, which occasions mutual disturbances. The *brain* alone, and with it knowing, pauses entirely in deep sleep. For it is merely the minister of foreign affairs, as the ganglion system is the minister of the interior. The brain, with its function of knowing, is only a *vedette* established by the will for its external ends, which, up in the watch-tower of the head, looks round through the windows of the senses and marks where mischief threatens and where advantages are to be looked for, and in accordance with whose report the will decides. This *vedette*, like every one engaged on active service, is then in a condition of strain and effort, and therefore it is glad when, after its watch is completed, it is again withdrawn, as every watch gladly retires from its post. This withdrawal is going to sleep, which is therefore so sweet and agreeable, and to which we are so glad to yield; on the other hand, being roused from sleep is

unwelcome, because it recalls the *vedette* suddenly to its post. One generally feels also after the beneficent systole the reappearance of the difficult diastole, the reseparation of the intellect from the will. A so-called *soul*, which was originally and radically a *knowing* being, would, on the contrary, necessarily feel on awaking like a fish put back into water. In sleep, when merely the vegetative life is carried on, the will works only according to its original and essential nature, undisturbed from without, with no diminution of its power through the activity of the brain and the exertion of knowing, which is the heaviest organic function, yet for the organism merely a means, not an end; therefore, in sleep the whole power of the will is directed to the maintenance and, where it is necessary, the improvement of the organism. Hence all healing, all favourable crises, take place in sleep; for the *vis naturæ medicatrix* has free play only when it is delivered from the burden of the function of knowledge. The embryo which has still to form the body therefore sleeps continuously, and the new-born child the greater part of its time. In this sense Burdach (*Physiologie*, vol. iii. p. 484) quite rightly declares sleep to be the *original state*.

With reference to the brain itself, I account to myself for the necessity of sleep more fully through an hypothesis which appears to have been first set up in Neumann's book, "*Von den Krankheiten des Menschen*," 1834, vol. 4, § 216. It is this, that the nutrition of the brain, thus the renewal of its substance from the blood, cannot go on while we are awake, because the very eminent organic function of knowing and thinking would be disturbed or put an end to by the low and material function of nutrition. This explains the fact that sleep is not a purely negative condition, a mere pausing of the activity of the brain, but also shows a positive character. This makes itself known through the circumstance that between sleep and waking there is no mere difference of degree, but a fixed boundary, which, as soon as sleep intervenes, declares itself in dreams which are completely different from our immediately preceding thoughts. A further proof of this is that when we have dreams which frighten us we try in vain to cry out, or to ward off attacks, or to shake off sleep; so that it is as if the connecting-link between the brain and the motor nerves, or between the cerebrum and the cerebellum (as the regulator of movements) were abolished; for the brain remains in its isolation and sleep holds us fast as with brazen claws. Finally, the positive character of sleep can be seen in the fact that a certain degree of strength is

required for sleeping. Therefore too great fatigue or natural weakness prevent us from seizing it, *capere somnum*. This may be explained from the fact that the *process of nutrition* must be introduced if sleep is to ensue: the brain must, as it were, begin to feed. Moreover, the increased flow of blood into the brain during sleep is explicable from the nutritive process; and also the position of the arms laid together above the head, which is instinctively assumed because it furthers this process: also why children, so long as their brain is still growing, require a great deal of sleep, while in old age, on the other hand, when a certain atrophy of the brain, as of all the parts, takes place, sleep is short; and finally why excessive sleep produces a certain dulness of consciousness, the consequence of a certain hypertrophy of the brain, which in the case of habitual excess of sleep may become permanent and produce imbecility: ανιη και πολυς ὑπνος (*noxæ est etiam multus somnus*), Od. 15, 394. The need of sleep is therefore directly proportionate to the intensity of the brain-life, thus to the clearness of the consciousness. Those animals whose brain-life is weak and dull sleep little and lightly; for example, reptiles and fishes: and here I must remind the reader that the winter sleep is sleep almost only in name, for it is not an inaction of the brain alone, but of the whole organism, thus a kind of apparent death. Animals of considerable intelligence sleep deeply and long. Men also require more sleep the more developed, both as regards quantity and quality, and the more active their brain is. Montaigne relates of himself that he had always been a long sleeper, that he had passed a large part of his life in sleeping, and at an advanced age still slept from eight to nine hours at a time (Liv. iii., chap. 13). Descartes also is reported to have slept a great deal (Baillet, *Vie de Descartes*, 1693, p. 288). Kant allowed himself seven hours for sleep, but it was so hard for him to do with this that he ordered his servant to force him against his will, and without listening to his remonstrances, to get up at the set time (Jachmann, *Immanuel Kant*, p. 162). For the more completely awake a man is, *i.e.*, the clearer and more lively his consciousness, the greater for him is the necessity of sleep, thus the deeper and longer he sleeps. Accordingly much thinking or hard brain-work increases the need of sleep. That sustained muscular exertion also makes us sleepy is to be explained from the fact that in this the brain continuously, by means of the *medulla oblongata*, the spinal marrow, and the motor nerves, imparts the stimulus to the muscles which affects their irritability, and in this way it exhausts its strength. The fatigue which we observe in the arms

and legs has accordingly its real seat in the brain; just as the pain which these parts feel is really experienced in the brain; for it is connected with the motor nerves, as with the nerves of sense. The muscles which are not actuated from the brain — for example, those of the heart — accordingly never tire. The same grounds explain the fact that both during and after great muscular exertion we cannot think acutely. That one has far less energy of mind in summer than in winter is partly explicable from the fact that in summer one sleeps less; for the deeper one has slept, the more completely awake, the more lively, is one afterwards. This, however, must not mislead us into extending sleep unduly, for then it loses in intension, *i.e.*, in deepness and soundness, what it gains in extension; whereby it becomes mere loss of time. This is what Goethe means when he says (in the second part of "Faust") of morning slumber: "Sleep is husk: throw it off." Thus in general the phenomenon of sleep most specially confirms the assertion that consciousness, apprehension, knowing, thinking, is nothing original in us, but a conditioned and secondary state. It is a luxury of nature, and indeed its highest, which it can therefore the less afford to pursue without interruption the higher the pitch to which it has been brought. It is the product, the efflorescence of the cerebral nerve-system, which is itself nourished like a parasite by the rest of the organism. This also agrees with what is shown in our third book, that knowing is so much the purer and more perfect the more it has freed and severed itself from the will, whereby the purely objective, the æsthetic comprehension appears. Just as an extract is so much the purer the more it has been separated from that out of which it is extracted and been cleared of all sediment. The opposite is shown by the *will*, whose most immediate manifestation is the whole organic life, and primarily the untiring heart.

This last consideration is related to the theme of the following chapter, to which it therefore makes the transition: yet the following observation belongs to it. In magnetic somnambulism the consciousness is doubled: two trains of knowledge, each connected in itself, but quite different from each other, arise; the waking consciousness knows nothing of the somnambulent. But the will retains in both the same character, and remains throughout identical; it expresses in both the same inclinations and aversions. For the function may be doubled, but not the true nature.

Chapter XX.[34] Objectification Of The Will In The Animal Organism.

By *objectification* I understand the self-exhibition in the real corporeal world. However, this world itself, as was fully shown in the first book and its supplements, is throughout conditioned by the knowing subject, thus by the intellect, and therefore as such is absolutely inconceivable outside the knowledge of this subject; for it primarily consists simply of ideas of perception, and as such is a phenomenon of the brain. After its removal the thing in itself would remain. That this is the *will* is the theme of the second book, and is there proved first of all in the human organism and in that of the brutes.

The knowledge of the external world may also be defined as the *consciousness of other things*, in opposition to *self-consciousness*. Since we have found in the latter that its true object or material is the will, we shall now, with the same intention, take into consideration the consciousness of other things, thus objective knowledge. Now here my thesis is this: *that which in self-consciousness, thus subjectively is the intellect, presents itself in the consciousness of other things, thus objectively, as the brain; and that which in self-consciousness, thus subjectively, is the will, presents itself in the consciousness of other things, thus objectively, as the whole organism*.

To the evidence which is given in support of this proposition, both in our second book and in the first two chapters of the treatise "*Ueber den Willen in der Natur*," I add the following supplementary remarks and illustrations.

Nearly all that is necessary to establish the first part of this thesis has already been brought forward in the preceding chapter, for in the necessity of sleep, in the alterations that arise from age, and in the differences of the anatomical conformation, it was proved that the intellect is of a secondary nature, and depends absolutely upon a single organ, the brain, whose function it is, just as grasping is the function of the hand; that it is therefore physical, like digestion, not metaphysical, like the will. As good digestion requires a healthy, strong stomach, as athletic power requires muscular sinewy arms, so extraordinary intelligence requires an unusually developed, beautifully formed brain of exquisitely fine texture and animated by a vigorous pulse. The nature of the will, on the contrary, is dependent upon no organ, and can be prognosticated from none. The greatest error in Gall's

phrenology is that he assigns organs of the brain for moral qualities also. Injuries to the head, with loss of brain substance, affect the intellect as a rule very disadvantageously: they result in complete or partial imbecility or forgetfulness of language, permanent or temporary, yet sometimes only of one language out of several which were known, also in the loss of other knowledge possessed, &c., &c. On the other hand, we never read that after a misfortune of this kind the *character* has undergone a change, that the man has perhaps become morally worse or better, or has lost certain inclinations or passions, or assumed new ones; never. For the will has not its seat in the brain, and moreover, as that which is metaphysical, it is the *prius* of the brain, as of the whole body, and therefore cannot be altered by injuries of the brain. According to an experiment made by Spallanzani and repeated by Voltaire,[35] a snail that has had its head cut off remains alive, and after some weeks a new head grows on, together with horns; with this consciousness and ideas again appear; while till then the snail had only given evidence of blind will through unregulated movements. Thus here also we find the will as the substance which is permanent, the intellect, on the contrary, conditioned by its organ, as the changing accident. It may be defined as the regulator of the will.

It was perhaps Tiedemann who first compared the cerebral nervous system to a *parasite* (*Tiedemann und Trevirann's Journal für Physiologie*, Bd. i. § 62). The comparison is happy; for the brain, together with the spinal cord and nerves which depend upon it, is, as it were, implanted in the organism, and is nourished by it without on its part *directly* contributing anything to the support of the economy of the organism; therefore there can be life without a brain, as in the case of brainless abortions, and also in the case of tortoises, which live for three weeks after their heads have been cut off; only the *medulla oblongata*, as the organ of respiration, must be spared. Indeed a hen whose whole brain Flourens had cut away lived for ten months and grew. Even in the case of men the destruction of the brain does not produce death directly, but only through the medium of the lungs, and then of the heart (*Bichat, Sur la Vie et la Mort*, Part ii., art. ii. § 1). On the other hand, the brain controls the relations to the external world; this alone is its office, and hereby it discharges its debt to the organism which nourishes it, since its existence is conditioned by the external relations. Accordingly the brain alone of all the parts requires sleep, because its *activity* is completely distinct from its *support*; the former only consumes both strength and

substance, the latter is performed by the rest of the organism as the nurse of the brain: thus because its activity contributes nothing to its continued existence it becomes exhausted, and only when it pauses in sleep does its nourishment go on unhindered.

The second part of our thesis, stated above, will require a fuller exposition even after all that I have said about it in the writings referred to. I have shown above, in chapter 18, that the thing in itself, which must lie at the foundation of every phenomenon, and therefore of our own phenomenal existence also, throws off in self-consciousness *one* of its phenomenal forms — space, and only retains the other — time. On this account it presents itself here more immediately than anywhere else, and we claim it as will, according to its most undisguised manifestation. But no *permanent substance*, such as matter is, can present itself in time alone, because, as § 4 of the first volume showed, such a substance is only possible through the intimate union of space and time. Therefore, in self-consciousness the will is not apprehended as the enduring substratum of its impulses, therefore is not perceived as a permanent substance; but only its individual acts, such as purposes, wishes, and emotions, are known successively and during the time they last, directly, yet not perceptibly. The knowledge of the will in self-consciousness is accordingly not a *perception* of it, but a perfectly direct becoming aware of its successive impulses. On the other hand, for the knowledge which is directed *outwardly*, brought about by the senses and perfected in the understanding, which, besides time, has also space for its form, which two it connects in the closest manner by means of the function of the understanding, causality, whereby it really becomes *perception* — this knowledge presents to itself *perceptibly* what in inner immediate apprehension was conceived as will, as *organic body*, whose particular movements visibly present to us the acts, and whose parts and forms visibly present to us the sustained efforts, the fundamental character, of the individually given will, nay, whose pain and comfort are perfectly immediate affections of this will itself.

We first become aware of this identity of the body with the will in the individual actions of the two, for in these what is known in self-consciousness as an immediate, real act of will, at the same time and unseparated, exhibits itself outwardly as movement of the body; and every one beholds the purposes of his will, which are instantaneously brought

about by motives which just as instantaneously appear at once as faithfully copied in as many actions of his body as his body itself is copied in his shadow; and from this, for the unprejudiced man, the knowledge arises in the simplest manner that his body is merely the outward manifestation of his will, *i.e.*, the way in which his will exhibits itself in his perceiving intellect, or his will itself under the form of the idea. Only if we forcibly deprive ourselves of this primary and simple information can we for a short time marvel at the process of our own bodily action as a miracle, which then rests on the fact that between the act of will and the action of the body there is really no causal connection, for they are directly *identical*, and their apparent difference only arises from the circumstance that here what is one and the same is apprehended in two different modes of knowledge, the outer and the inner. Actual willing is, in fact, inseparable from doing and in the strictest sense only that is an act of will which the deed sets its seal to. Mere resolves of the will, on the contrary, till they are carried out, are only intentions, and are therefore matter of the intellect alone; as such they have their place merely in the brain, and are nothing more than completed calculations of the relative strength of the different opposing motives. They have, therefore, certainly great probability, but no infallibility. They may turn out false, not only through alteration of the circumstances, but also from the fact that the estimation of the effect of the respective motives upon the will itself was erroneous, which then shows itself, for the deed is untrue to the purpose: therefore before it is carried out no resolve is certain. The *will itself*, then, is operative only in real action; hence in muscular action, and consequently in *irritability*. Thus the *will* proper objectifies itself in this. The cerebrum is the place of motives, where, through these, the will becomes choice, *i.e.*, becomes more definitely determined by motives. These motives are ideas, which, on the occasion of external stimuli of the organs of sense, arise by means of the functions of the brain, and are also worked up into conceptions, and then into resolves. When it comes to the real act of will these motives, the workshop of which is the cerebrum, act through the medium of the cerebellum upon the spinal cord and the motor nerves which proceed from it, which then act upon the muscles, yet merely as *stimuli* of their irritability; for galvanic, chemical, and even mechanical stimuli can effect the same contraction which the motor nerve calls forth. Thus what was *motive* in the brain acts, when it reaches the muscle through the nerves, as mere stimulus. Sensibility in itself is quite unable to contract

a muscle. This can only be done by the muscle itself, and its capacity for doing so is called *irritability*, *i.e.*, *susceptibility to stimuli*. It is exclusively a property of the muscle, as sensibility is exclusively a property of the nerve. The latter indeed gives the muscle the *occasion* for its contraction, but it is by no means it that, in some mechanical way, draws the muscle together; but this happens simply and solely on account of the *irritability*, which is a power of the muscle itself. Apprehended from without this is a *Qualitas occulta*, and only self-consciousness reveals it as the *will*. In the causal chain here briefly set forth, from the effect of the motive lying outside us to the contraction of the muscle, the will does not in some way come in as the last link of the chain; but it is the metaphysical substratum of the irritability of the muscle: thus it plays here precisely the same part which in a physical or chemical chain of causes is played by the mysterious forces of nature which lie at the foundation of the process — forces which as such are not themselves involved as links in the causal chain, but impart to all the links of it the capacity to act, as I have fully shown in § 26 of the first volume. Therefore we would ascribe the contraction of the muscle also to a similar mysterious force of nature, if it were not that this contraction is disclosed to us by an entirely different source of knowledge — self-consciousness as *will*. Hence, as was said above, if we start from the will our own muscular movement appears to us a miracle; for indeed there is a strict causal chain from the external motive to the muscular action; but the will itself is not included as a link in it, but, as the metaphysical substratum of the possibility of an action upon the muscle through brain and nerve, lies at the foundation of the present muscular action also; therefore the latter is not properly its *effect* but its *manifestation*. As such it enters the world of idea, the form of which is the law of causality, a world which is entirely different from the *will* in itself: and thus, if we start from the *will*, this manifestation has, for attentive reflection, the appearance of a miracle, but for deeper investigation it affords the most direct authentication of the great truth that what appears in the phenomenon as body and its action is in itself *will*. If now perhaps the motor nerve that leads to my hand is severed, the will can no longer move it. This, however, is not because the hand has ceased to be, like every part of my body, the objectivity, the mere visibility, of my will, or in other words, that the irritability has vanished, but because the effect of the motive, in consequence of which alone I can move my hand, cannot reach it and act on its muscles as a stimulus, for the line of connection

between it and the brain is broken. Thus really my will is, in this part, only deprived of the effect of the motive. The will objectifies itself directly, in irritability, not in sensibility.

In order to prevent all misunderstandings about this important point, especially such as proceed from physiology pursued in a purely empirical manner, I shall explain the whole process somewhat more thoroughly. My doctrine asserts that the whole body is the will itself, exhibiting itself in the perception of the brain; consequently, having entered into its forms of knowledge. From this it follows that the will is everywhere equally present in the whole body, as is also demonstrably the case, for the organic functions are its work no less than the animal. But how, then, can we reconcile it with this, that the *voluntary* actions, those most undeniable expressions of the will, clearly originate in the brain, and thus only through the spinal cord reach the nerve fibres, which finally set the limbs in motion, and the paralysis or severing of which therefore prevents the possibility of voluntary movement? This would lead one to think that the will, like the intellect, has its seat only in the brain, and, like it, is a mere function of the brain.

Yet this is not the case: but the whole body is and remains the exhibition of the will in perception, thus the will itself objectively perceived by means of the functions of the brain. That process, however, in the case of the acts of will, depends upon the fact that the will, which, according to my doctrine, expresses itself in every phenomenon of nature, even in vegetable and inorganic phenomena, appears in the bodies of men and animals as a *conscious will*. A *consciousness*, however, is essentially a unity, and therefore always requires a central point of unity. The necessity of consciousness is, as I have often explained, occasioned by the fact that in consequence of the increased complication, and thereby more multifarious wants, of an organism, the acts of its will must be guided by *motives*, no longer, as in the lower grades, by mere stimuli. For this purpose it had at this stage to appear provided with a knowing consciousness, thus with an intellect, as the medium and place of the motives. This intellect, if itself objectively perceived, exhibits itself as the brain, together with its appendages, spinal cord, and nerves. It is the brain now in which, on the occasion of external impressions, the ideas arise which become motives for the will. But in the *rational* intellect they undergo besides this a still further working up, through reflection and deliberation. Thus such an intellect must

first of all unite in *one* point all impressions, together with the working up of them by its functions, whether to mere perception or to conceptions, a point which will be, as it were, the focus of all its rays, in order that that unity of consciousness may arise which is the the *theoretical ego*, the supporter of the whole consciousness, in which it presents itself as identical with the *willing ego*, whose mere function of knowledge it is. That point of unity of consciousness, or the theoretical ego, is just Kant's synthetic unity of apperception, upon which all ideas string themselves as on a string of pearls, and on account of which the "I think," as the thread of the string of pearls, "must be capable of accompanying all our ideas."[36] This assembling-place of the motives, then, where their entrance into the single focus of consciousness takes place, is the brain. Here, in the non-rational consciousness, they are merely perceived; in the *rational* consciousness they are elucidated by conceptions, thus are first thought in the abstract and compared; upon which the will chooses, in accordance with its individual and immutable character, and so the *purpose* results which now, by means of the cerebellum, the spinal cord, and the nerves, sets the outward limbs in motion. For although the will is quite directly present in these, inasmuch as they are merely its manifestation, yet when it has to move according to motives, or indeed according to reflection, it requires such an apparatus for the apprehension and working up of ideas into such motives, in conformity with which its acts here appear as resolves: just as the nourishment of the blood with chyle requires a stomach and intestines, in which this is prepared, and then as such is poured into the blood through the *ductus thoracicus*, which here plays the part which the spinal cord plays in the former case. The matter may be most simply and generally comprehended thus: the will is immediately present as irritability in all the muscular fibres of the whole body, as a continual striving after activity in general. Now if this striving is to realise itself, thus to manifest itself as movement, this movement must as such have some direction; but this direction must be *determined* by something, *i.e.*, it requires a guide, and this is the nervous system. For to the mere irritability, as it lies in the muscular fibres and in itself is pure will, all directions are alike; thus it determines itself in no direction, but behaves like a body which is equally drawn in all directions; it remains at rest. Since the activity of the nerves comes in as motive (in the case of reflex movements as a stimulus), the striving force, *i.e.*, the irritability, receives a definite direction, and now produces the movements.

Yet those external acts of will which require no motives, and thus also no working up of mere stimuli into ideas in the brain, from which motives arise, but which follow immediately upon stimuli, for the most part inward stimuli, are the reflex movements, starting only from the spinal cord, as, for example, spasms and cramp, in which the will acts without the brain taking part. In an analogous manner the will carries on the organic life, also by nerve stimulus, which does not proceed from the brain. Thus the will appears in every muscle as irritability, and is consequently of itself in a position to contract them, yet only *in general*; in order that some definite contraction should take place at a given moment, there is required here, as everywhere, a cause, which in this case must be a stimulus. This is everywhere given by the nerve which goes into the muscle. If this nerve is in connection with the brain, then the contraction is a conscious act of will, *i.e.*, takes place in accordance with motives, which, in consequence of *external* impressions, have arisen as ideas in the brain. If the nerve is *not* in connection with the brain, but with the *sympathicus maximus*, then the contraction is involuntary and unconscious, an act connected with the maintenance of the organic life, and the nerve stimulus which causes it is occasioned by *inward* impressions; for example, by the pressure upon the stomach of the food received, or of the chyme upon the intestines, or of the in-flowing blood upon the walls of the heart, in accordance with which the act is digestion, or *motus peristalticus*, or beating of the heart, &c.

But if now, in this process, we go one step further, we find that the muscles are the product of the blood, the result of its work of condensation, nay, to a certain extent they are merely solidified, or, as it were, clotted or crystallised blood; for they have taken up into themselves, almost unaltered, its fibrin (*cruor*) and its colouring matter (*Burdach's Physiologie*, Bd. v. § 686). But the force which forms the muscle out of the blood must not be assumed to be different from that which afterwards moves it as irritability, upon nerve stimulus, which the brain supplies; in which case it then presents itself in self-consciousness as that which we call *will*. The close connection between the blood and irritability is also shown by this, that where, on account of imperfection of the lesser circulation, part of the blood returns to the heart unoxidised, the irritability is also uncommonly weak, as in the batrachia. Moreover, the movement of the blood, like that of the muscle, is independent and original; it does not, like irritation, require the influence of the nerve, and is even independent of the heart, as is shown

most clearly by the return of the blood through the veins to the heart; for here it is not propelled by a *vis a tergo*, as in the case of the arterial circulation; and all other mechanical explanations, such as a power of suction of the right ventricle of the heart, are quite inadequate. (See *Burdach's Physiologie*, Bd. 4, § 763, and *Rösch, Ueber die Bedeutung des Blutes, § II, seq.*) It is remarkable to see how the French, who recognise nothing but mechanical forces, controvert each other with insufficient grounds upon both sides; and Bichat ascribes the flowing back of the blood through the veins to the pressure of the walls of the capillary tubes, and Magendie, on the other hand, to the continue action of the impulse of the heart (*Précis de Physiologie par Magendie*, vol. ii. p. 389). That the movement of the blood is also independent of the nervous system, at least of the cerebral nervous system, is shown by the fetus, which (according to *Müller's Physiologie*), without brain and spinal cord, has yet circulation of the blood. And Flourens also says: "*Le mouvement du cœur, pris en soi, et abstraction faite de tout ce qui n'est pas essentiellement lui, comme sa durée, son énergie, ne dépend ni immédiatement, ni coinstantanément, du système nerveux central, et conséquemment c'est dans tout autre point de ce système que dans les centres nerveux eux-mêmes, qu'il faut chercher le principe primitif et immédiat de ce mouvement*" (*Annales des sciences naturelles p. Audouin et Brougniard*, 1828, vol. 13). Cuvier also says: "*La circulation survit à la déstruction de tout l'encéphale et de toute la moëlle épiniaire* (*Mém. de l'acad. d. sc.*, 1823, vol. 6; *Hist. d. l'acad. p. Cuvier*," p. cxxx). "*Cor primum vivens et ultimum moriens*," says Haller. The beating of the heart ceases at last in death. The blood has made the vessels themselves; for it appears in the ovum earlier than they do; they are only its path, voluntarily taken, then beaten smooth, and finally gradually condensed and closed up; as Kaspar Wolff has already taught: "*Theorie der Generation*," § 30-35. The motion of the heart also, which is inseparable from that of the blood, although occasioned by the necessity of sending blood into the lungs, is yet an original motion, for it is independent of the nervous system and of sensibility, as Burdach fully shows. "In the heart," he says, "appears, with the maximum of irritability, a minimum of sensibility" (*loc. cit.*, § 769). The heart belongs to the muscular system as well as to the blood or vascular system; from which, however, it is clear that the two are closely related, indeed constitute one whole. Since now the metaphysical substratum of the

force which moves the muscle, thus of irritability, is the *will*, the will must also be the metaphysical substratum of the force which lies at the foundation of the movement and the formations of the blood, as that by which the muscles are produced. The course of the arteries also determines the form and size of all the limbs; consequently the whole form of the body is determined by the course of the blood. Thus in general the blood, as it nourishes all the parts of the body, has also, as the primary fluidity of the organism, produced and framed them out of itself. And the nourishment which confessedly constitutes the principal function of the blood is only the continuance of that original production of them. This truth will be found thoroughly and excellently explained in the work of Rösch referred to above: "*Ueber die Bedeutung des Blutes*," 1839. He shows that the blood is that which first has life and is the source both of the existence and of the maintenance of all the parts; that all the organs have sprung from it through secretion, and together with them, for the management of their functions, the nervous system, which appears now as *plastic*, ordering and arranging the life of the particular parts within, now as *cerebral*, controlling the relation to the external world. "The blood," he says, p. 25, "was flesh and nerve at once, and at the same moment at which the muscle freed itself from it the nerve, severed in like manner, remained opposed to the flesh." Here it is a matter of course that the blood, before those solid parts have been secreted from it, has also a somewhat different character from afterwards; it is then, as Rösch defines it, the chaotic, animated, slimy, primitive fluid, as it were an organic emulsion, in which all subsequent parts are *implicite* contained: moreover, it has not the red colour quite at the beginning. This disposes of the objection which might be drawn from the fact that the brain and the spinal cord begin to form before the circulation of the blood is visible or the heart appears. In this reference also Schultz says (*System der Circulation*, § 297): "We do not believe that the view of Baūmgärten, according to which the nervous system is formed earlier than the blood, can consistently be carried out; for Baūmgärten reckons the appearance of the blood only from the formation of the corpuscles, while in the embryo and in the series of animals blood appears much earlier in the form of a pure plasma." The blood of invertebrate animals never assumes the red colour; but we do not therefore, with Aristotle, deny that they have any. It is well worthy of note that, according to the account of Justinus Kerner (*Geschichte zweier Somnambulen*, § 78), a somnambulist of a very high degree of

clairvoyance, says: “I am as deep in myself as ever a man can be led; the force of my mortal life seems to me to have its source in the blood, whereby, through the circulation in the veins, it communicates itself, by means of the nerves, to the whole body, and to the brain, which is the noblest part of the body, and above the blood itself.”

From all this it follows that the will objectifies itself most immediately in the blood as that which originally makes and forms the organism, perfects it by growth, and afterwards constantly maintains it, both by the regular renewal of all the parts and by the extraordinary restoration of any part that may have been injured. The first productions of the blood are its own vessels, and then the muscles, in the irritability of which the will makes itself known to self-consciousness; but with this also the heart, which is at once vessel and muscle, and therefore is the true centre and *primum mobile* of the whole life. But for the individual life and subsistence in the external world the will now requires two assistant systems: *one* to govern and order its inner and outer activity, and *another* for the constant renewal of the mass of the blood; thus a controller and a sustainer. It therefore makes for itself the nervous and the intestinal systems; thus the *functiones animales* and the *functiones naturales* associate themselves in a subsidiary manner with the *functiones vitales*, which are the most original and essential. In the *nervous system*, accordingly, the will only objectifies itself in an indirect and secondary way; for this system appears as a mere auxiliary organ, as a contrivance by means of which the will attains to a knowledge of those occasions, internal and external, upon which, in conformity with its aims, it must express itself; the internal occasions are received by the *plastic* nervous system, thus by the sympathetic nerve, this *cerebrum abdominale*, as mere stimuli, and the will thereupon reacts on the spot without the brain being conscious; the *outward* occasions are received by the brain, as *motives*, and the will reacts through conscious actions directed outwardly. Therefore the whole nervous system constitutes, as it were, the antennæ of the will, which it stretches towards within and without. The nerves of the brain and spinal cord separate at their roots into sensory and motory nerves. The sensory nerves receive the knowledge from without, which now accumulates in the thronging brain, and is there worked up into ideas, which arise primarily as motives. But the motory nerves bring back, like couriers, the result of the brain function to the muscle, upon which it acts as a stimulus, and the irritability of which is the immediate manifestation of the

will. Presumably the plastic nerves also divide into sensory and motory, although on a subordinate scale. The part which the ganglia play in the organism we must think of as that of a diminutive brain, and thus the one throws light upon the other. The ganglia lie wherever the organic functions of the vegetative system require care. It is as if there the will was not able by its direct and simple action to carry out its aims, but required guidance, and consequently control; just as when in some business a man's own memory is not sufficient, and he must constantly take notes of what he does. For this end mere knots of nerves are sufficient for the interior of the organism, because everything goes on within its own compass. For the exterior, on the other hand, a very complicated contrivance of the same kind is required. This is the brain with its feelers, which it stretches into the outer world, the nerves of sense. But even in the organs which are in communication with this great nerve centre, in very simple cases the matter does not need to be brought before the highest authority, but a subordinate one is sufficient to determine what is needed; such is the spinal cord, in the reflex actions discovered by Marshall Hall, such as sneezing, yawning, vomiting, the second half of swallowing, &c. &c. The will itself is present in the whole organism, since this is merely its visible form; the nervous system exists everywhere merely for the purpose of making the *direction* of an action possible by a control of it, as it were to serve the will as a mirror, so that it may see what it does, just as we use a mirror to shave by. Hence small sensoria arise within us for special, and consequently simple, functions, the ganglia; but the chief sensorium, the brain, is the great and skilfully contrived apparatus for the complicated and multifarious functions which have to do with the ceaselessly and irregularly changing external world. Wherever in the organism the nerve threads run together in a ganglion, there, to a certain extent, an animal exists for itself and shut off, which by means of the ganglion has a kind of weak knowledge, the sphere of which is, however, limited to the part from which these nerves directly come. But what actuates these parts to such *quasi* knowledge is clearly the *will*; indeed we are utterly unable to conceive it otherwise. Upon this depends the *vita propria* of each part, and also in the case of insects, which, instead of a spinal cord, have a double string of nerves, with ganglia at regular intervals, the capacity of each part to continue alive for days after being severed from the head and the rest of the trunk; and finally also the actions which in the last instance do not receive their motives from the

brain, *i.e.*, instinct and natural mechanical skill. Marshall Hall, whose discovery of the reflex movements I have mentioned above, has given us in this the *theory of involuntary movements*. Some of these are normal or physiological; such are the closing of the places of ingress to and egress from the body, thus of the *sphincteres vesicæ et ani* (proceeding from the nerves of the spinal cord); the closing of the eyelids in sleep (from the fifth pair of nerves), of the larynx (from *N. vagus*) if food passes over it or carbonic acid tries to enter; also swallowing, from the pharynx, yawning and sneezing, respiration, entirely in sleep and partly when awake; and, lastly, the erection, ejaculation, as also conception, and many more. Some, again, are abnormal and pathological; such are stammering, hiccoughing, vomiting, also cramps and convulsions of every kind, especially in epilepsy, tetanus, in hydrophobia and otherwise; finally, the convulsive movements produced by galvanic or other stimuli, and which take place without feeling or consciousness in paralysed limbs, *i.e.*, in limbs which are out of connection with the brain, also the convulsions of beheaded animals, and, lastly, all movements and actions of children born without brains. All cramps are a rebellion of the nerves of the limbs against the sovereignty of the brain; the normal reflex movements, on the other hand, are the legitimate autocracy of the subordinate officials. These movements are thus all involuntary, because they do not proceed from the brain, and therefore do not take place in accordance with motives, but follow upon mere stimuli. The stimuli which occasion them extend only to the spinal cord or the *medulla oblongata*, and from there the reaction directly takes place which effects the movement. The spinal cord has the same relation to these involuntary movements as the brain has to motive and action, and what the sentient and voluntary nerve is for the latter the incident and motor nerve is for the former. That yet, in the one as in the other, that which really moves is the *will* is brought all the more clearly to light because the involuntarily moved muscles are for the most part the same which, under other circumstances, are moved from the brain in the voluntary actions, in which their *primum mobile* is intimately known to us through self-consciousness as the *will*. Marshall Hall's excellent book "On the Diseases of the Nervous System" is peculiarly fitted to bring out clearly the difference between volition and will, and to confirm the truth of my fundamental doctrine.

For the sake of illustrating all that has been said, let us now call to mind that case of the origination of an organism which is most accessible to our

observation. Who makes the chicken in the egg? Some power and skill coming from without, and penetrating through the shell? Oh no! The chicken makes itself, and the force which carries out and perfects this work, which is complicated, well calculated, and designed beyond all expression, breaks through the shell as soon as it is ready, and now performs the outward actions of the chicken, under the name of *will*. It cannot do both at once; previously occupied with the perfecting of the organism, it had no care for without. But after it has completed the former, the latter appears, under the guidance of the brain and its feelers, the senses, as a tool prepared beforehand for this end, the service of which only begins when it grows up in self-consciousness as intellect, which is the lantern to the steps of the will, its ἡγεμονικον, and also the supporter of the objective external world, however limited the horizon of this may be in the consciousness of a hen. But what the hen is now able to do in the external world, through the medium of this organ, is, as accomplished by means of something secondary, infinitely less important than what it did in its original form, for it made itself.

We became acquainted above with the cerebral nervous system as an *assistant organ* of the will, in which it therefore objectifies itself in a secondary manner. As thus the cerebral system, although not directly coming within the sphere of the life-functions of the organism, but only governing its relations to the outer world, has yet the organism as its basis, and is nourished by it in return for its services; and as thus the cerebral or animal life is to be regarded as the production of the organic life, the brain and its function, knowledge, thus the intellect, belong indirectly and in a subordinate manner to the manifestation of the *will*. The will objectifies itself also in it, as will to apprehend the external world, thus as *will to know*. Therefore great and fundamental as is the difference in us between willing and knowing, the ultimate substratum of both is yet the same, the *will*, as the real inner nature of the whole phenomenon. But knowing, the intellect, which presents itself in self-consciousness entirely as secondary, is to be regarded not only as the accident of the will, but also as its work, and thus, although in a circuitous manner, is yet to be referred to it. As the intellect presents itself physiologically as the function of an organ of the body, metaphysically it is to be regarded as a work of the will, whose objectification or visible appearance is the whole body. Thus the will *to know*, objectively perceived, is the brain; as the will *to go*, objectively

perceived, is the foot; the will *to grasp*, the hand; the will *to digest*, the stomach; the will *to beget*, the genitals, &c. This whole objectification certainly ultimately exists only for the brain, as its perception: in this the will exhibits itself as organised body. But so far as the brain knows, it is *itself* not known, but is the *knower*, the subject of all knowledge. So far, however, as in objective perception, *i.e.*, in the consciousness of *other things*, thus secondarily, *it is known*, it belongs, as an organ of the body, to the objectification of the will. For the whole process is the *self-knowledge of the will*; it starts from this and returns to it, and constitutes what Kant has called the *phenomenon* in opposition to the thing in itself. Therefore that which is *known*, that which is *idea*, is the *will*; and this idea is what we call body, which, as extended in space and moving in time, exists only by means of the functions of the brain, thus only in it. That, on the other hand, which *knows*, which *has that idea*, is the *brain*, which yet does not know itself, but only becomes conscious of itself subjectively as intellect, *i.e.*, as the *knower*. That which when regarded from within is the faculty of knowledge is when regarded from without the brain. This brain is a part of that body, just because it itself belongs to the objectification of the *will*, the will's *will to know* is objectified in it, its tendency towards the external world. Accordingly the brain, and therefore the intellect, is certainly conditioned immediately by the body, and this again by the brain, yet only indirectly, as spatial and corporeal, in the world of perception, not in itself, *i.e.*, as will. Thus the whole is ultimately the will, which itself becomes idea, and is that unity which we express by I. The brain itself, so far as it is *perceived* — thus in the consciousness of other things, and hence secondarily — is only idea. But in itself, and so far as it *perceives*, it is the will, because this is the real substratum of the whole phenomenon; its will to know objectifies itself as brain and its functions. We may take the voltaic pile as an illustration, certainly imperfect, but yet to some extent throwing light upon the nature of the human phenomenon, as we here regard it. The metals, together with the fluid, are the body; the chemical action, as the basis of the whole effect, is the will, and the electric current resulting from it, which produces shock and spark, is the intellect. But *omne simile claudicat*.

Quite recently the *physiatrica* point of view has at last prevailed in pathology. According to it diseases are themselves a curative process of nature, which it introduces to remove, by overcoming its causes, a disorder

which in some way has got into the organism. Thus in the decisive battle, the crisis, it is either victorious and attains its end, or else is defeated. This view only gains its full rationality from our standpoint, which shows the *will* in the vital force, that here appears as *vis naturœ medicatrix*, the will which lies at the foundation of all organic functions in a healthy condition, but now, when disorder has entered, threatening its whole work, assumes dictatorial power in order to subdue the rebellious forces by quite extraordinary measures and entirely abnormal operations (the disease), and bring everything back to the right track. On the other hand, that the *will itself* is sick, as Brandis repeatedly expresses himself in his book, "*Ueber die Anwendung der Kälte*," which I have quoted in the first part of my essay, "*Ueber den Willen in der Natur*," is a gross misunderstanding. When I weigh this, and at the same time observe that in his earlier book, "*Ueber die Lebenskraft*," of 1795, Brandis betrayed no suspicion that this force is in itself the will, but, on the contrary, says there, page 13: "It is impossible that the vital force can be that which we only know through our consciousness, for most movements take place without our consciousness. The assertion that this, of which the only characteristic known to us is consciousness, also affects the body without consciousness is at the least quite arbitrary and unproved;" and page 14: "Haller's objections to the opinion that all living movements are the effect of the soul are, as I believe, quite unanswerable;" when I further reflect that he wrote his book, "*Ueber die Anwendung der Kälte*," in which all at once the will appears so decidedly as the vital force, in his seventieth year, an age at which no one as yet has conceived for the first time original fundamental thoughts; when, lastly, I bear in mind that he makes use of my exact expressions, "will and idea," and not of those which are far more commonly used by others, "the faculties of desire and of knowledge," I am now convinced, contrary to my earlier supposition, that he borrowed his fundamental thought from me, and with the usual honesty which prevails at the present day in the learned world, said nothing about it. The particulars about this will be found in the second (and third) edition of my work, "*Ueber den Willen in der Natur*," p. 14.

Nothing is more fitted to confirm and illustrate the thesis with which we are occupied in this chapter than Bichat's justly celebrated book, "*Sur la vie et la mort*." His reflections and mine reciprocally support each other, for his are the physiological commentary on mine, and mine are the philosophical commentary on his, and one will best understand us both by reading us

together. This refers specially to the first half of his work, entitled "*Recherches physiologiques sur la vie*." He makes the foundation of his expositions the opposition of the *organic* to the *animal* life, which corresponds to mine of the will to the intellect. Whoever looks at the sense, not at the words, will not allow himself to be led astray by the fact that he ascribes the will to the animal life; for by will, as is usual, he only understands conscious volition, which certainly proceeds from the brain, where, however, as was shown above, it is not yet actual willing, but only deliberation upon and estimation of the motives, the conclusion or product of which at last appears as the act of will. All that I ascribe to the *will* proper he ascribes to the *organic* life, and all that I conceive as *intellect* is with him the *animal* life: the latter has with him its seat in the brain alone, together with its appendages: the former, again, in the whole of the remainder of the organism. The complete opposition in which he shows that the two stand to each other corresponds to that which with me exists between the will and the intellect. As anatomist and physiologist he starts from the objective, that is, from the consciousness of other things; I, as a philosopher, start from the subjective, self-consciousness; and it is a pleasure to see how, like the two voices in a duet, we advance in harmony with each other, although each expresses something different. Therefore, let every one who wishes to understand me read him; and let every one who wishes to understand him, better than he understood himself, read me. Bichat shows us, in article 4, that the *organic* life begins earlier and ends later than the *animal* life; consequently, since the latter also rests in sleep, has nearly twice as long a duration; then, in articles 8 and 9, that the organic life performs everything perfectly, at once, and of its own accord; the animal life, on the other hand, requires long practice and education. But he is most interesting in the sixth article, where he shows that the *animal* life is completely limited to the intellectual operations, therefore goes on coldly and indifferently, while the emotions and passions have their seat in the *organic* life, although the occasions of them lie in the animal, *i.e.*, the cerebral, life. Here he has ten valuable pages which I wish I could quote entire. On page 50 he says: "*Il est sans doute étonnant, que les passions n'ayent jamais leur terme ni leur origine dans les divers organs de la vie animale; qu'au contraire les parties servant aux fonctions internes, soient constamment affectées par elles, et même les déterminent suivant l'état où*

elles se trouvent. Tel est cependant ce que la stricte observation nous prouve. Je dis d'abord que l'effet de toute espèce de passion, constamment étranger à la vie animale, est de faire naître un changement, une altération quelconque dans la vie organique." Then he shows in detail how anger acts on the circulation of the blood and the beating of the heart, then how joy acts, and lastly how fear; next, how the lungs, the stomach, the intestines, the liver, glands, and pancreas are affected by these and kindred emotions, and how grief diminishes the nutrition; and then how the animal, that is, the brain life, is untouched by all this, and quietly goes on its way. He refers to the fact that to signify intellectual operations we put the hand to the head, but, on the contrary, we lay it on the heart, the stomach, the bowels, if we wish to express our love, joy, sorrow, or hatred; and he remarks that he must be a bad actor who when he spoke of his grief would touch his head, and when he spoke of his mental effort would touch his heart; and also that while the learned make the so-called soul reside in the head, the common people always indicate the well-felt difference between the affections of the intellect and the will by the right expression, and speak, for example, of a capable, clever, fine head; but, on the other hand, say a good heart, a feeling heart, and also "Anger boils in my veins," "Stirs my gall," "My bowels leap with joy," "Jealousy poisons my blood," &c. "*Les chants sont le langage des passions, de la vie organique, comme la parole ordinaire est celui de l'entendement, de la vie animale: la déclamation, tient le milieu, elle anime la langue froide du cerveau par la langue expressive des organes intérieurs, du cœur, du foie, de l'estomac*," &c. His conclusion is: "*La vie organique est le terme où aboutissent, et le centre d'où partent les passions*." Nothing is better fitted than this excellent and thorough book to confirm and bring out clearly that the body is only the embodied (*i.e.*, perceived by means of the brain functions, time, space, and causality) will itself, from which it follows that the will is the primary and original, the intellect, as mere brain function, the subordinate and derived. But that which is most worthy of admiration, and to me most pleasing, in Bichat's thought is, that this great anatomist, on the path of his purely physiological investigations, actually got so far as to explain the unalterable nature of the *moral character* from the fact that only the *animal* life, thus the functions of the brain, are subject to the influence of education, practice, culture, and habit, but the moral character belongs to the *organic* life, *i.e.*, to all the other parts, which cannot

be modified from without. I cannot refrain from giving the passage; it occurs in article 9, § 2: "*Telle est donc la grande différence des deux vies de l'animal*" (cerebral or animal and organic life) "*par rapport à l'inégalité de perfection des divers systèmes de fonctions, dont chacune résulte; savoir, que dans l'une la prédominance ou l'infériorité d'un système relativement aux autres, tient presque toujours à l'activité ou à l'inertie plus grandes de ce système, à l'habitude d'agir ou de ne pas agir; que dans l'autre, au contraire, cette prédominance ou cette infériorité sont immédiatement liées a la texture des organes, et jamais à leur éducation. Voilà pourquoi le tempérament physique et le* charactère moral *ne sont point susceptible de changer par l'éducation, qui modifie si prodigieusement les actes de la vie animale; car, comme nous l'avons vu, tous deux* appartiennent à la vie organique. *La charactère est, si je puis m'exprimer ainsi, la physionomie des passions; le tempérament est celle des fonctions internes: or les unes et les autres étant toujours les mêmes, ayant une direction que l'habitude et l'exercice ne dérangent jamais, il est manifeste que le tempérament et le charactère doivent être aussi soustraits à l'empire de l'éducation. Elle peut modérer l'influence du second, perfectionner assez le jugement et la réflection, pour rendre leur empire supérieur au sien, fortifier la vie animal afin qu'elle résiste aux impulsions de l'organique. Mais vouloir par elle dénaturer le charactère, adoucir ou exalter les passions dont il est l'expression habituelle, agrandir ou resserrer leur sphère, c'est une entreprise analogue a celle d'un médecin qui essaierait d'élever ou d'abaisser de quelque degrés, et pour toute la vie, la force de contraction ordinaire au cœur dans l'état de santé, de précipiter ou de ralentir habituellement le mouvement naturel aux artères, et qui est nécessaire à leur action, etc. Nous observerions à ce médecin, que la circulation, la respiration, etc., ne sont point sous le domaine de la volonté* (volition), *quelles ne peuvent être modifiées par l'homme, sans passer à l'état maladif, etc. Faisons la même observation à ceux qui croient qu'on change le charactère, et par-là, même les* passions, *puisque celles-ci sont un* produit de l'action de tous les organes internes, *ou qu'elles y ont au moins spécialement leur siège.*" The reader who is familiar with my philosophy may imagine how great was my joy when I discovered, as it were, the proof of my own convictions in those which were arrived at upon an entirely different field, by this extraordinary man, so early taken from the world.

A special authentication of the truth that the organism is merely the visibility of the will is also afforded us by the fact that if dogs, cats, domestic cocks, and indeed other animals, bite when violently angry, the wounds become mortal; nay, if they come from a dog, may cause hydrophobia in the man who is bitten, without the dog being mad or afterwards becoming so. For the extremest anger is only the most decided and vehement will to annihilate its object; this now appears in the assumption by the saliva of an injurious, and to a certain extent magically acting, power, and springs from the fact that the will and the organism are in truth one. This also appears from the fact that intense vexation may rapidly impart to the mother's milk such a pernicious quality that the sucking child dies forthwith in convulsions (*Most, Ueber sympathetische Mittel*, p. 16).

Note On What Has Been Said About Bichat.

Bichat has, as we have shown above, cast a deep glance into human nature, and in consequence has given an exceedingly admirable exposition, which is one of the most profound works in the whole of French literature. Now, sixty years later, M. Flourens suddenly appears with a polemic against it in his work, "*De la vie et de l'intelligence*," and makes so bold as to declare without ceremony that all that Bichat has brought to light on this important subject, which was quite his own, is false. And what does he oppose to him in the field? Counter reasons? No, counter assertions[37] and authorities, indeed, which are as inadmissible as they are remarkable — Descartes and Gall! M. Flourens is by conviction a Cartesian, and to him Descartes, in the year 1858, is still "*le philosophe par excellence*." Now Descartes was certainly a great man, yet only as a forerunner. In the whole of his dogmas, on the other hand, there is not a word of truth; and to appeal to these as authorities at this time of day is simply absurd. For in the nineteenth century a Cartesian in philosophy is just what a follower of Ptolemy would be in astronomy, or a follower of Stahl in chemistry. But for M. Flourens the dogmas of Descartes are articles of faith. Descartes has taught, *les volontés sont des pensées*: therefore this is the case, although every one feels within himself that willing and thinking are as different as white and black. Hence I have been able above, in chapter 19, to prove and explain this fully and thoroughly, and always under the guidance of experience. But above all, according to Descartes, the oracle of M. Flourens, there are two fundamentally different substances, body and soul. Consequently M. Flourens, as an orthodox Cartesian, says: "*Le premier point est de séparer, même par les mots, ce qui est du corps de ce qui est de l'âme*" (i. 72). He informs us further that this "*âme réside uniquement et exclusivement dans le cerveau*" (ii. 137); from whence, according to a passage of Descartes, it sends the *spiritus animales* as couriers to the muscles, yet can only itself be affected by the brain; therefore the passions have their seat (*siège*) in the heart, which is altered by them, yet their place (*place*) in the brain. Thus, really thus, speaks the oracle of M. Flourens, who is so much edified by it, that he even utters it twice after him (i. 33 and ii. 135), for the unfailing conquest of the ignorant Bichat, who knows neither soul nor body, but merely an animal and an organic life, and whom he then here

condescendingly informs that we must thoroughly distinguish the parts where the passions have their *seat* (*siègent*) from those which they *affect*. According to this, then, the passions *act* in one place while they *are* in another. Corporeal things are wont to act only where they are, but with an immaterial soul the case may be different. But what in general may he and his oracle really have thought in this distinction of *place* and *siège*, of *sièger* and *affecter*? The fundamental error of M. Flourens and Descartes springs really from the fact that they confound the motives or occasions of the passions, which, as ideas, certainly lie in the intellect, *i.e.*, in the brain, with the passions themselves, which, as movements of the will, lie in the whole body, which (as we know) is the perceived will itself. M. Flourens' second authority is, as we have said, Gall. I certainly have said, at the beginning of this twentieth chapter (and already in the earlier edition): "The greatest error in Gall's phrenology is, that he makes the brain the organ of moral qualities also." But what I censure and reject is precisely what M. Flourens praises and admires, for he bears in his heart the doctrine of Descartes: "*Les volontés sont des pensées.*" Accordingly he says, p. 144: "*Le premier service que Gall a rendu à la physiologie (?) a éte de rammener le moral à l'intellectuel, et de faire voir que les facultés morales et les facultés intellectuelles sont du même ordre, et de les placer toutes, autant les unes que les autres, uniquement et exclusivement dans le cerveau.*" To a certain extent my whole philosophy, but especially the nineteenth chapter of this volume, consists of the refutation of this fundamental error. M. Flourens, on the contrary, is never tired of extolling this as a great truth and Gall as its discoverer; for example, p. 147: "*Si j'en étais à classer les services que nous a rendu Gall, je dirais que le premier a été de rammener les qualités morales au cerveau*;" — p. 153: "*Le cerveau seul est l'organe de l'âme, et de l'âme dans toute la plénitude de ses fonctions*" (we see the simple soul of Descartes still always lurks in the background, as the kernel of the matter); "*il est le siège de toutes les facultés intellectuelles.... Gall a rammené* le moral a l'intellectuel, *il a rammené les qualités morales au même siège, au même organe, que les facultés intellectuelles*." Oh how must Bichat and I be ashamed of ourselves in the presence of such wisdom! But, to speak seriously, what can be more disheartening, or rather more shocking, than to see the true and profound rejected and the false and perverse extolled; to live to find that important truths, deeply hidden, and extracted late and with

difficulty, are to be torn down, and the old, stale, and late conquered errors set up in their place; nay, to be compelled to fear that through such procedure the advances of human knowledge, so hardly achieved, will be broken off! But let us quiet our fears; for *magma est vis veritatis et prævalebit*. M. Flourens is unquestionably a man of much merit, but he has chiefly acquired it upon the experimental path. Just those truths, however, which are of the greatest importance cannot be brought out by experiments, but only by reflection and penetration. Now Bichat by his reflection and penetration has here brought a truth to light which is of the number of those which are unattainable by the experimental efforts of M. Flourens, even if, as a true and consistent Cartesian, he tortures a hundred more animals to death. But he ought betimes to have observed and thought something of this: "Take care, friend, for it burns." The presumption and self-sufficiency, however, such as is only imparted by superficiality combined with a false obscurity, with which M. Flourens undertakes to refute a thinker like Bichat by counter assertions, old wives' beliefs, and futile authorities, indeed to reprove and instruct him, and even almost to mock at him, has its origin in the nature of the Academy and its *fauteuils*. Throned upon these, and saluting each other mutually as *illustre confrère*, gentlemen cannot avoid making themselves equal with the best who have ever lived, regarding themselves as oracles, and therefore fit to decree what shall be false and what true. This impels and entitles me to say out plainly for once, that the really superior and privileged minds, who now and then are born for the enlightenment of the rest, and to whom certainly Bichat belongs, are so "by the grace of God," and accordingly stand to the Academy (in which they have generally occupied only the forty-first *fauteuil*) and to its *illustres confrères*, as born princes to the numerous representatives of the people, chosen from the crowd. Therefore a secret awe should warn these gentlemen of the Academy (who always exist by the score) before they attack such a man, — unless they have most cogent reasons to present, and not mere contradictions and appeals to *placita* of Descartes, which at the present day is quite absurd.

ENDNOTES.

1.

Bruno and Spinoza are here entirely to be excepted. They stand each for himself and alone, and belong neither to their age nor their quarter of the globe, which rewarded the one with death and the other with persecution and insult. Their miserable existence and death in this Western world is like that of a tropical plant in Europe. The banks of the sacred Ganges were their true spiritual home; there they would have led a peaceful and honoured life among men of like mind. In the following lines, with which Bruno begins his book *Della Causa Principio et Uno*, for which he was brought to the stake, he expresses clearly and beautifully how lonely he felt himself in his age, and he also shows a presentiment of his fate which led him to delay the publication of his views, till that inclination to communicate what one knows to be true, which is so strong in noble minds, prevailed:

"*Ad partum properare tuum, mens ægra, quid obstat;*
Seclo hæc indigno sint tribuenda licet?
Umbrarum fluctu terras mergente, cacumen
Adtolle in clarum, noster Olympe, Jovem."

Whoever has read this his principal work, and also his other Italian writings, which were formerly so rare, but are now accessible to all through a German edition, will find, as I have done, that he alone of all philosophers in some degree approaches to Plato, in respect of the strong blending of poetical power and tendency along with the philosophical, and this he also shows especially in a dramatic form. Imagine the tender, spiritual, thoughtful being, as he shows himself to us in this work of his, in the hands of coarse, furious priests as his judges and executioners, and thank Time which brought a brighter and a gentler age, so that the after-world whose curse was to fall on those fiendish fanatics is the world we now live in.

4.

Observe here that I always quote the “Kritik der reinen Vernunft” according to the paging of the first edition, for in Rosenkranz’s edition of Kant’s collected works this paging is always given in addition. Besides this, I add the paging of the fifth edition, preceded by a V.; all the other editions, from the second onwards, are the same as the fifth, and so also is their paging.

5.

Cf. Christian Wolf’s “*Vernünftige Gedanken von Gott, Welt und Seele*,” § 577-579. It is strange that he only explains as contingent what is necessary according to the principle of sufficient reason of becoming, *i.e.*, what takes place from causes, and on the contrary recognises as necessary that which is so according to the other forms of the principle of sufficient reason; for example, what follows from the *essentia* (definition), thus analytical judgments, and further also mathematical truths. The reason he assigns for this is, that only the law of causality gives infinite series, while the other kinds of grounds give only finite series. Yet this is by no means the case with the forms of the principle of sufficient reason in pure space and time, but only holds good of the logical ground of knowledge; but he held mathematical necessity to be such also. Compare the essay on the principle of sufficient reason, § 50.

6.

With my refutation of the Kantian proof may be compared the earlier attacks upon it by Feder, *Ueber Zeit, Raum und Kausalität*, § 28; and by G. E. Schulze, *Kritik der theoretischen Philosophie*, Bd. ii. S. 422-442.

8.

That the assumption of a limit of the world in time is certainly not a necessary thought of the reason may be also proved historically, for the Hindus teach nothing of the kind, even in the religion of the people, much less in the Vedas, but try to express mythologically by means of monstrous chronology the infinity of this phenomenal world, this fleeting and baseless web of Mâyâ, for they at once bring out very ingeniously the relativity of all periods of time in the following mythus (Polier, *Mythologie des Indous*, vol. ii. p. 585). The four ages, in the last of which we live, embrace together 4,320,000 years. Each day of the creating Brahma has 1000 such periods of four ages, and his nights have also

1000. His year has 365 days and as many nights. He lives 100 of his years, always creating; and if he dies, at once a new Brahma is born, and so on from eternity to eternity. The same relativity of time is also expressed in the special myth which is quoted in Polier's work, vol. ii. p. 594, from the Puranas. In it a Rajah, after a visit of a few seconds to Vishnu in his heaven, finds on his return to earth that several millions of years have elapsed, and a new age has begun; for every day of Vishnu is 100 recurrences of the four ages.

9.

Kant said, "It is very absurd to expect enlightenment from reason, and yet to prescribe to her beforehand which side she must necessarily take" ("Critique of Pure Reason," p. 747; V. 775). On the other hand, the following is the naive assertion of a professor of philosophy in our own time: "If a philosophy denies the reality of the fundamental ideas of Christianity, it is either false, or, *even if true, it is yet useless*." That is to say, for professors of philosophy. It was the late Professor Bachmann who, in the Jena *Litteraturzeitung* for July 1840, No. 126, so indiscreetly blurted out the maxim of all his colleagues. However, it is worth noticing, as regards the characteristics of the University philosophy, how here the truth, if it will not suit and adapt itself, is shown the door without ceremony, with, "Be off, truth! we cannot make *use* of you. Do we owe you anything? Do you pay us? Then be off!"

10.

By the way, Machiavelli's problem was the solution of the question how the prince, *as a prince*, was to keep himself on the throne in spite of internal and external enemies. His problem was thus by no means the ethical problem whether a prince, as a man, ought to will such things, but purely the political one how, if he so wills, he can carry it out. And the solution of this problem he gives just as one writes directions for playing chess, with which it would be folly to mix up the answer to the question whether from an ethical point of view it is advisable to play chess at all. To reproach Machiavelli with the immorality of his writing is just the same as to reproach a fencing-master because he does not begin his instructions with a moral lecture against murder and slaughter.

11.

Although the conception of legal right is properly negative in opposition to that of wrong, which is the positive starting-point, yet the explanation of these conceptions must not on this account be entirely negative.

12.

I specially recommend here the passage in Lichtenberg's "Miscellaneous Writings" (Göthingen, 1801, vol. ii. p. 12): "Euler says, in his letters upon various subjects in connection with natural science (vol. ii. p. 228), that it would thunder and lighten just as well if there were no man present whom the lightning might strike. It is a very common expression, but I must confess that it has never been easy for me completely to comprehend it. It always seems to me as if the conception *being* were something derived from our thought, and thus, if there are no longer any sentient and thinking creatures, then there is nothing more whatever."

13.

Lichtenberg says in his "*Nachrichten und Bemerkungen von und über sich selbst*" (*Vermischte Schriften, Göttingen*, 1800, vol. i. p. 43): "I am extremely sensitive to all noise, but it entirely loses its disagreeable character as soon as it is associated with a rational purpose."

14.

That the three-toed sloth has nine must be regarded as a mistake; yet Owen still states this, "*Ostéologie Comp.*," p. 405.

15.

This, however, does not excuse a professor of philosophy who, sitting in Kant's chair, expresses himself thus: "That mathematics as such contains arithmetic and geometry is correct. It is incorrect, however, to conceive arithmetic as the science of time, really for no other reason than to give a pendant (*sic*) to geometry as the science of space" (Rosenkranz in the "*Deutschen Museum*," 1857, May 14, No. 20). This is the fruit of Hegelism. If the mind is once thoroughly debauched with its senseless jargon, serious Kantian philosophy will no longer enter it. The audacity to talk at random about what one does not understand has been inherited from the master, and one comes in the end to condemn without ceremony the fundamental teaching of a great genius in a tone of peremptory decision, just as if it were Hegelian foolery. We must not, however, fail to notice that these little people struggle to escape from the track of great thinkers. They would therefore have done better not to attack Kant, but to content themselves with giving their public full details about God, the soul, the actual freedom of the will, and whatever belongs to that sort of thing, and then to have indulged in a private luxury in their dark back-shop, the philosophical journal; there they may do whatever they like without constraint, for no one sees it.

A principal use of the study of the ancients is that it preserves us from *verbosity*; for the ancients always take pains to write concisely and pregnantly, and the error of almost all moderns is verbosity, which the most recent try to make up for by suppressing syllables and letters. Therefore we ought to pursue the study of the ancients all our life, although reducing the time devoted to it. The ancients knew that we ought not to write as we speak. The moderns, on the other hand, are not even ashamed to print lectures they have delivered.

It is remarkable that Augustine already knew this. In the fourteenth book, "*De Civ. Dei*," c. 6, he speaks of the *affectionibus animi*, which in the preceding book he had brought under four categories, *cupiditas*, *timor*, *lætitia*, *tristitia*, and says: "*Voluntas est quippe in omnibus, imo omnes nihil aliud, quam voluntates sunt: nam quid est cupiditas et lætitia, nisi voluntas in eorum consensionem, quæ volumus? et quid est metus atque tristitia, nisi voluntas in dissensionem ab his, quæ nolumus? cet.*"

32.

By those who place mind and learning above all other human qualities this man will be reckoned the greatest of his century. But by those who let virtue take precedence of everything else his memory can never be execrated enough. He was the cruelest of the citizens in persecuting, putting to death, and banishing.

« Tout ce qui est relatif à l'entendement appartient à la vie animale, » dit Bichat, et jusque-là point de doute; « tout ce qui est relatif aux passions appartient à la vie organique, » — et ceci est absolument faux. Indeed! — *decrevit Florentius magnus*.

VOLUME III.

Supplements To The Second Book.

Chapter XXI. Retrospect and More General View.

If the intellect were not of a subordinate nature, as the two preceding chapters show, then everything which takes place without it, *i.e.*, without intervention of the idea, such as reproduction, the development and maintenance of the organism, the healing of wounds, the restoration or vicarious supplementing of mutilated parts, the salutary crisis in diseases, the works of the mechanical skill of animals, and the performances of instinct would not be done so infinitely better and more perfectly than what takes place with the assistance of intellect, all conscious and intentional achievements of men, which compared with the former are mere bungling. In general nature signifies that which operates, acts, performs without the assistance of the intellect. Now, that this is really identical with what we find in ourselves as will is the general theme of this second book, and also of the essay, "*Ueber den Willen in der Natur*." The possibility of this fundamental knowledge depends upon the fact that in us the will is directly lighted by the intellect, which here appears as self-consciousness; otherwise we could just as little arrive at a fuller knowledge of it within us as without us, and must for ever stop at inscrutable forces of nature. We have to abstract from the assistance of the intellect if we wish to comprehend the nature of the will in itself, and thereby, as far as is possible, penetrate to the inner being of nature.

On this account, it may be remarked in passing, my direct antipode among philosophers is Anaxagoras; for he assumed arbitrarily as that which is first and original, from which everything proceeds, a νους, an intelligence, a subject of ideas, and he is regarded as the first who promulgated such a view. According to him the world existed earlier in the mere idea than in itself; while according to me it is the unconscious will which constitutes the reality of things, and its development must have advanced very far before it finally attains, in the animal consciousness, to the idea and intelligence; so that, according to me, thought appears as the very last. However, according to the testimony of Aristotle (*Metaph.*, i. 4), Anaxagoras himself did not know how to begin much with his νους, but merely set it up, and then left it standing like a painted saint at the entrance, without making use of it in his development of nature, except in cases of need, when he did not know how else to help himself. All physico-theology is a carrying out of the error opposed to the truth expressed at the beginning

of this chapter — the error that the most perfect form of the origin of things is that which is brought about by means of an intellect. Therefore it draws a bolt against all deep exploration of nature.

From the time of Socrates down to our own time, we find that the chief subject of the ceaseless disputations of the philosophers has been that ens rationis, called soul. We see the most of them assert its immortality, that is to say, its metaphysical nature; yet others, supported by facts which incontrovertibly prove the entire dependence of the intellect upon the bodily organism, unweariedly maintain the contrary. That soul is by all and before everything taken as absolutely simple; for precisely from this its metaphysical nature, its immateriality and immortality were proved, although these by no means necessarily follow from it. For although we can only conceive the destruction of a formed body through breaking up of it into its parts, it does not follow from this that the destruction of a simple existence, of which besides we have no conception, may not be possible in some other way, perhaps by gradually vanishing. I, on the contrary, start by doing away with the presupposed simplicity of our subjectively conscious nature, or the ego, inasmuch as I show that the manifestations from which it was deduced have two very different sources, and that in any case the intellect is physically conditioned, the function of a material organ, therefore dependent upon it, and without it is just as impossible as the grasp without the hand; that accordingly it belongs to the mere phenomenon, and thus shares the fate of this, — that the will, on the contrary, is bound to no special organ, but is everywhere present, is everywhere that which moves and forms, and therefore is that which conditions the whole organism; that, in fact, it constitutes the metaphysical substratum of the whole phenomenon, consequently is not, like the intellect, a Posterius of it, but its Prius; and the phenomenon depends upon it, not it upon the phenomenon. But the body is reduced indeed to a mere idea, for it is only the manner in which the will exhibits itself in the perception of the intellect or brain. The will, again, which in all other systems, different as they are in other respects, appears as one of the last results, is with me the very first. The intellect, as mere function of the brain, is involved in the destruction of the body, but the will is by no means so. From this heterogeneity of the two, together with the subordinate nature of the intellect, it becomes conceivable that man, in the depths of his self-consciousness, feels himself to be eternal and indestructible, but yet can have no memory, either a parte ante or a

parte post, beyond the duration of his life. I do not wish to anticipate here the exposition of the true indestructibility of our nature, which has its place in the fourth book, but have only sought to indicate the place where it links itself on.

But now that, in an expression which is certainly one-sided, yet from our standpoint true, the body is called a mere idea depends upon the fact than an existence in space, as something extended, and in time, as something that changes, and more closely determined in both through the causal-nexus, is only possible in the idea, for all those determinations rest upon its forms, thus in a brain, in which accordingly such an existence appears as something objective, *i.e.*, foreign; therefore even our own body can have this kind of existence only in a brain. For the knowledge which I have of my body as extended, space-occupying, and movable, is only indirect: it is a picture in my brain which is brought about by means of the senses and understanding. The body is given to me directly only in muscular action and in pain and pleasure, both of which primarily and directly belong to the will. But the combination of these two different kinds of knowledge of my own body afterwards affords the further insight that all other things which also have the objective existence described, which is primarily only in my brain, are not therefore entirely non-existent apart from it, but must also ultimately in themselves be that which makes itself known in self-consciousness as will.

Chapter XXII.[1] Objective View of the Intellect.

There are two fundamentally different ways of regarding the intellect, which depend upon the difference of the point of view, and, much as they are opposed to each other in consequence of this, must yet be brought into agreement. One is the subjective, which, starting from within and taking the consciousness as the given, shows us by what mechanism the world exhibits itself in it, and how, out of the materials which the senses and the understanding provide, it constructs itself in it. We must look upon Locke as the originator of this method of consideration; Kant brought it to incomparably higher perfection; and our first book also, together with its supplements, are devoted to it.

The method of considering the intellect which is opposed to this is the objective, which starts from without, takes as its object not our own consciousness, but the beings given in outward experience, conscious of themselves and of the world, and now investigates the relation of their intellect to their other qualities, how it has become possible, how it has become necessary, and what it accomplishes for them. The standpoint of this method of consideration is the empirical. It takes the world and the animal existences present in it as absolutely given, in that it starts from them. It is accordingly primarily zoological, anatomical, physiological, and only becomes philosophical by connection with that first method of consideration, and from the higher point of view thereby attained. The only foundations of this which as yet have been given we owe to zootomists and physiologists, for the most part French. Here Cabanis is specially to be named, whose excellent work, "*Des rapports du physique au moral*," is initiatory of this method of consideration on the path of physiology. The famous Bichat was his contemporary, but his theme was a much more comprehensive one. Even Gall may be named here, although his chief aim was missed. Ignorance and prejudice have raised against this method of consideration the accusation of materialism, because, adhering simply to experience, it does not know the immaterial substance, soul. The most recent advances in the physiology of the nervous system, through Sir Charles Bell, Magendie, Marshall Hall, and others, have also enriched and corrected the material of this method of consideration. A philosophy which, like the Kantian, entirely ignores this point of view for the intellect is one-

sided, and consequently inadequate. It leaves an impassable gulf between our philosophical and our physiological knowledge, with which we can never find satisfaction.

Although what I have said in the two preceding chapters concerning the life and the activity of the brain belongs to this method of consideration, and in the same way all the discussions to be found under the heading, "*Pflanzenphysiologie*," in the essay, "*Ueber den Willen in der Natur*," and also a portion of those under the heading "*Vergleichende Anatomie*," are devoted to it, the following exposition of its results in general will be by no means superfluous.

We become most vividly conscious of the glaring contrast between the two methods of considering the intellect opposed to each other above if we carry the matter to the extreme and realise that what the one, as reflective thought and vivid perception, directly assumes and makes its material is for the other nothing more than the physiological function of an internal organ, the brain; nay, that we are justified in asserting that the whole objective world, so boundless in space, so infinite in time, so unsearchable in its perfection, is really only a certain movement or affection of the pulpy matter in the skull. We then ask in astonishment: what is this brain whose function produces such a phenomenon of all phenomena? What is the matter which can be refined and potentiated to such a pulp that the stimulation of a few of its particles becomes the conditional supporter of the existence of an objective world? The fear of such questions led to the hypothesis of the simple substance of an immaterial soul, which merely dwelt in the brain. We say boldly: this pulp also, like every vegetable or animal part, is an organic structure, like all its poorer relations in the inferior accommodation of the heads of our irrational brethren, down to the lowest, which scarcely apprehends at all; yet that organic pulp is the last product of nature, which presupposes all the rest. But in itself, and outside the idea, the brain also, like everything else, is will. For existing for another is being perceived; being in itself is willing: upon this it depends that on the purely objective path we never attain to the inner nature of things; but if we attempt to find their inner nature from without and empirically, this inner always becomes an outer again in our hands, — the pith of the tree, as well as its bark; the heart of the animal, as well as its hide; the white and the yolk of an egg, as well as its shell. On the other hand, upon the subjective path the inner is accessible to us at every moment; for we find it as the will

primarily in ourselves, and must, by the clue of the analogy with our own nature, be able to solve that of others, in that we attain to the insight that a being in itself independent of being known, *i.e.*, of exhibiting itself in an intellect, is only conceivable as willing.

If now, in the objective comprehension of the intellect, we go back as far as we possibly can, we shall find that the necessity or the need of knowledge in general arises from the multiplicity and the separate existence of beings, thus from individuation. For suppose there only existed a single being, such a being would have no need of knowledge: because nothing would exist which was different from it, and whose existence it would therefore have to take up into itself indirectly through knowledge, *i.e.*, image and concept. It would itself already be all in all, and therefore there would remain nothing for it to know, *i.e.*, nothing foreign that could be apprehended as object. In the case of a multiplicity of beings, on the other hand, every individual finds itself in a condition of isolation from all the rest, and hence arises the necessity of knowledge. The nervous system, by means of which the animal individual primarily becomes conscious of itself, is bounded by a skin; yet in the brain that has attained to intellect it passes beyond this limit by means of its form of knowledge, causality, and thus there arises for it perception as a consciousness of other things, as an image of beings in space and time, which change in accordance with causality. In this sense it would be more correct to say, “Only the different is known by the different,” than as Empedocles said, “Only the like is known by the like,” which was a very indefinite and ambiguous proposition; although points of view may certainly also be conceived from which it is true; as, for instance, we may observe in passing that of Helvetius when he says so beautifully and happily: “Il n’y a que l’esprit qui sente l’esprit: c’est une corde qui ne frémit qu’à l’unison,” which corresponds with Xenophon’s “σοφον ειναι δει τον επιγνωσομενον τον σοφον” (sapientem esse opportet eum, qui sapientem agniturus sit), and is a great sorrow. But now, again, from the other side we know that multiplicity of similars only becomes possible through time and space; thus through the forms of our knowledge. Space first arises in that the knowing subject sees externally; it is the manner in which the subject comprehends something as different from itself. But we also saw knowledge in general conditioned by multiplicity and difference. Thus knowledge and multiplicity, or individuation, stand and fall together, for they reciprocally condition each

other. Hence it must be inferred that, beyond the phenomenon in the true being of all things, to which time and space, and consequently also multiplicity, must be foreign, there can also be no knowledge. Buddhism defines this as Pratschna Paramita, *i.e.*, that which is beyond all knowledge (J. J. Schmidt, "On the Maha-Jana and Pratschna Paramita"). A "knowledge of things in themselves," in the strictest sense of the word, would accordingly be already impossible from the fact that where the thing in itself begins knowledge ceases, and all knowledge is essentially concerned only with phenomena. For it springs from a limitation, by which it is made necessary, in order to extend the limits.

For the objective consideration the brain is the efflorescence of the organism; therefore only where the latter has attained its highest perfection and complexity does the brain appear in its greatest development. But in the preceding chapter we have recognised the organism as the objectification of the will; therefore the brain also, as a part of it, must belong to this objectification. Further, from the fact that the organism is only the visibility of the will, thus in itself is the will, I have deduced that every affection of the organism at once and directly affects the will, *i.e.*, is felt as agreeable or painful. Yet, with the heightening of sensibility, in the higher development of the nervous system, the possibility arises that in the nobler, *i.e.*, the objective, organs of sense (sight and hearing) the exquisitely delicate affections proper to them are perceived without in themselves and directly affecting the will, that is, without being either painful or agreeable, and that therefore they appear in consciousness as indifferent, merely perceived, sensations. But in the brain this heightening of sensibility reaches such a high degree that upon received impressions of sense a reaction even takes place, which does not proceed directly from the will, but is primarily a spontaneity of the function of understanding, which makes the transition from the directly perceived sensation of the senses to its cause; and since the brain then at once produces the form of space, there thus arises the perception of an external object. We may therefore regard the point at which the understanding makes the transition from the mere sensation upon the retina, which is still a mere affection of the body and therefore of the will, to the cause of that sensation, which it projects by means of its form of space, as something external and different from its own body, as the boundary between the world as will and the world as idea, or as the birthplace of the latter. In man, however, the spontaneity of the activity of

the brain, which in the last instance is certainly conferred by the will, goes further than mere perception and immediate comprehension of causal relations. It extends to the construction of abstract conceptions out of these perceptions, and to operating with these conceptions, *i.e.*, to thinking, as that in which his reason consists. Thoughts are therefore furthest removed from the affections of the body, which, since the body is the objectification of the will, may, through increased intensity, pass at once into pain, even in the organs of sense. Accordingly idea and thought may also be regarded as the efflorescence of the will, because they spring from the highest perfection and development of the organism; but the organism, in itself and apart from the idea, is the will. Of course, in my explanation, the existence of the body presupposes the world of idea; inasmuch as it also, as body or real object, is only in this world; and, on the other hand, the idea itself just as much presupposes the body, for it arises only through the function of an organ of the body. That which lies at the foundation of the whole phenomenon, that in it which alone has being in itself and is original, is exclusively the will; for it is the will which through this very process assumes the form of the idea, *i.e.*, enters the secondary existence of an objective world, or the sphere of the knowable. Philosophers before Kant, with few exceptions, approached the explanation of the origin of our knowledge from the wrong side. They set out from a so-called soul, an existence whose inner nature and peculiar function consisted in thinking, and indeed quite specially in abstract thinking, with mere conceptions, which belonged to it the more completely the further they lay from all perception. (I beg to refer here to the note at the end of § 6 of my prize essay on the foundation of morals.) This soul has in some inconceivable manner entered the body, and there it is only disturbed in its pure thinking, first by impressions of the senses and perceptions, still more by the desires which these excite, and finally by the emotions, nay, passions, to which these desires develop; while the characteristic and original element of this soul is mere abstract thinking, and given up to this it has only universals, inborn conceptions, and æternæ veritates for its objects, and leaves everything perceptible lying far below it. Hence, also, arises the contempt with which even now "sensibility" and the "sensuous" are referred to by professors of philosophy, nay, are even made the chief source of immorality, while it is just the senses which are the genuine and innocent source of all our knowledge, from which all thinking must first borrow its material, for in

combination with the a priori functions of the intellect they produce the perception. One might really suppose that in speaking of sensibility these gentlemen always think only of the pretended sixth sense of the French. Thus, as we have said, in the process of knowledge, its ultimate product was made that which is first and original in it, and accordingly the matter was taken hold of by the wrong end. According to my exposition, the intellect springs from the organism, and thereby from the will, and hence could not be without the latter. Thus, without the will it would also find no material to occupy it; for everything that is knowable is just the objectification of the will.

But not only the perception of the external world, or the consciousness of other things, is conditioned by the brain and its functions, but also self-consciousness. The will in itself is without consciousness, and remains so in the greater part of its phenomena. The secondary world of idea must be added, in order that it may become conscious of itself, just as light only becomes visible through the bodies which reflect it, and without them loses itself in darkness without producing any effect. Because the will, with the aim of comprehending its relations to the external world, produces a brain in the animal individual, the consciousness of its own self arises in it, by means of the subject of knowledge, which comprehends things as existing and the ego as willing. The sensibility, which reaches its highest degree in the brain, but is yet dispersed through its different parts, must first of all collect all the rays of its activity, concentrate them, as it were, in a focus, which, however, does not lie without, as in the case of the concave mirror, but within, as in the convex mirror. With this point now it first describes the line of time, upon which, therefore, all that it presents to itself as idea must exhibit itself, and which is the first and most essential form of all knowledge, or the form of inner sense. This focus of the whole activity of the brain is what Kant called the synthetic unity of apperception (cf. vol. ii. p. 475). Only by means of this does the will become conscious of itself, because this focus of the activity of the brain, or that which knows, apprehends itself as identical with its own basis, from which it springs, that which wills; and thus the ego arises. Yet this focus of the brain activity remains primarily a mere subject of knowledge, and as such capable of being the cold and impartial spectator, the mere guide and counsellor of the will, and also of comprehending the external world in a purely objective manner, without reference to the will and its weal or woe. But whenever it

turns within, it recognises the will as the basis of its own phenomenon, and therefore combines with it in the consciousness of an ego. That focus of the activity of the brain (or the subject of knowledge) is indeed, as an indivisible point, simple, but yet is not on this account a substance (soul), but a mere condition or state. That of which it is itself a condition or state can only be known by it indirectly, as it were through reflection. But the ceasing of this state must not be regarded as the annihilation of that of which it is a state. This knowing and conscious ego is related to the will, which is the basis of its phenomenal appearance, as the picture in the focus of a concave mirror is related to the mirror itself, and has, like that picture, only a conditioned, nay, really a merely apparent, reality. Far from being the absolutely first (as, for example, Fichte teaches), it is at bottom tertiary, for it presupposes the organism, and the organism presupposes the will. I admit that all that is said here is really only an image and a figure, and in part also hypothetical; but we stand at a point to which thought can scarcely reach, not to speak of proof. I therefore request the reader to compare with this what I have adduced at length on this subject in chapter 20.

Now, although the true being of everything that exists consists in its will, and knowledge together with consciousness are only added at the higher grades of the phenomenon as something secondary, yet we find that the difference which the presence and the different degree of consciousness places between one being and another is exceedingly great and of important results. The subjective existence of the plant we must think of as a weak analogue, a mere shadow of comfort and discomfort; and even in this exceedingly weak degree the plant knows only of itself, not of anything outside of it. On the other hand, even the lowest animal standing next to it is forced by increased and more definitely specified wants to extend the sphere of its existence beyond the limits of its own body. This takes place through knowledge. It has a dim apprehension of its immediate surroundings, out of which the motives for its action with a view to its own maintenance arise. Thus accordingly the medium of motives appears, and this is — the world existing objectively in time and space, the world as idea, however weak, obscure, and dimly dawning this first and lowest example of it may be. But it imprints itself ever more and more distinctly, ever wider and deeper, in proportion as in the ascending scale of animal organisations the brain is ever more perfectly produced. This progress in the development of the brain, thus of the intellect, and of the clearness of the idea, at each of

these ever higher grades is, however, brought about by the constantly increasing and more complicated wants of this phenomenon of the will. This must always first afford the occasion for it, for without necessity nature (*i.e.*, the will which objectifies itself in it) produces nothing, least of all the hardest of its productions — a more perfect brain: in consequence of its lex parsimoniæ: natura nihil agit frustra et nihil facit supervacaneum. It has provided every animal with the organs which are necessary for its sustenance and the weapons necessary for its conflict, as I have shown at length in my work, "*Ueber den Willen in der Natur*," under the heading, "*Vergleichende Anatomie*." According to this measure, therefore, it imparts to each the most important of those organs concerned with what is without, the brain, with its function the intellect. The more complicated, through higher development, its organisation became, the more multifarious and specially determined did its wants also become, and consequently the more difficult and the more dependent upon opportunity was the provision of what would satisfy them. Thus there was needed here a wider range of sight, a more accurate comprehension, a more correct distinction of things in the external world, in all their circumstances and relations. Accordingly we see the faculty of forming ideas, and its organs, brain, nerves, and special senses, appear ever more perfect the higher we advance in the scale of animals; and in proportion as the cerebral system develops, the external world appears ever more distinct, many-sided, and complete in consciousness. The comprehension of it now demands ever more attention, and ultimately in such a degree that sometimes its relation to the will must momentarily be lost sight of in order that it may take place more purely and correctly. Quite definitely this first appears in the case of man. With him alone does a pure separation of knowing and willing take place. This is an important point, which I merely touch on here in order to indicate its position, and be able to take it up again later. But, like all the rest, nature takes this last step also in extending and perfecting the brain, and thereby in increasing the powers of knowledge, only in consequence of the increased needs, thus in the service of the will. What this aims at and attains in man is indeed essentially the same, and not more than what is also its goal in the brutes — nourishment and propagation. But the requisites for the attainment of this goal became so much increased in number, and of so much higher quality and greater definiteness through the organisation of man, that a very much more considerable heightening of the intellect than the previous steps

demanded was necessary, or at least was the easiest means of reaching the end. But since now the intellect, in accordance with its nature, is a tool of the most various utility, and is equally applicable to the most different kinds of ends, nature, true to her spirit of parsimony, could now meet through it alone all the demands of the wants which had now become so manifold. Therefore she sent forth man without clothing, without natural means of protection or weapons of attack, nay, with relatively little muscular power, combined with great frailty and little endurance of adverse influences and wants, in reliance upon that one great tool, in addition to which she had only to retain the hands from the next grade below him, the ape. But through the predominating intellect which here appears not only is the comprehension of motives, their multiplicity, and in general the horizon of the aims infinitely increased, but also the distinctness with which the will is conscious of itself is enhanced in the highest degree in consequence of the clearness of the whole consciousness which has been brought about, which is supported by the capacity for abstract knowledge, and now attains to complete reflectiveness. But thereby, and also through the vehemence of the will, which is necessarily presupposed as the supporter of such a heightened intellect, an intensifying of all the emotions appears, and indeed the possibility of the passions, which, properly speaking, are unknown to the brute. For the vehemence of the will keeps pace with the advance of intelligence, because this advance really always springs from the increased needs and pressing demands of the will: besides this, however, the two reciprocally support each other. Thus the vehemence of the character corresponds to the greater energy of the beating of the heart and the circulation of the blood, which physically heighten the activity of the brain. On the other hand, the clearness of the intelligence intensifies the emotions, which are called forth by the outward circumstances, by means of the more vivid apprehension of the latter. Hence, for example, young calves quietly allow themselves to be packed in a cart and carried off; but young lions, if they are only separated from their mother, remain permanently restless, and roar unceasingly from morning to night; children in such a position would cry and vex themselves almost to death. The vivaciousness and impetuosity of the ape is in exact proportion to its greatly developed intellect. It depends just on this reciprocal relationship that man is, in general, capable of far greater sorrows than the brute, but also of greater joy in satisfied and pleasing emotions. In the same way his higher intelligence makes him more

sensible to ennui than the brute; but it also becomes, if he is individually very complete, an inexhaustible source of entertainment. Thus, as a whole, the manifestation of the will in man is related to that in the brute of the higher species, as a note that has been struck to its fifth pitched two or three octaves lower. But between the different kinds of brutes also the differences of intellect, and thereby of consciousness, are great and endlessly graduated. The mere analogy of consciousness which we must yet attribute to plants will be related to the still far deader subjective nature of an unorganised body, very much as the consciousness of the lowest species of animals is related to the quasi consciousness of plants. We may present to our imagination the innumerable gradations in the degree of consciousness under the figure of the different velocity of points which are unequally distant from the centre of a revolving sphere. But the most correct, and indeed, as our third book teaches, the natural figure of that gradation is afforded us by the scale in its whole compass from the lowest audible note to the highest. It is, however, the grade of consciousness which determines the grade of existence of a being. For every immediate existence is subjective: the objective existence is in the consciousness of another, thus only for this other, consequently quite indirect. Through the grade of consciousness beings are as different as through the will they are alike, for the will is what is common to them all.

But what we have now considered between the plant and the animal, and then between the different species of animals, occurs also between man and man. Here also that which is secondary, the intellect, by means of the clearness of consciousness and distinctness of knowledge which depends upon it, constitutes a fundamental and immeasurably great difference in the whole manner of the existence, and thereby in the grade of it. The higher the consciousness has risen, the more distinct and connected are the thoughts, the clearer the perceptions the more intense the sensations. Through it everything gains more depth: emotion, sadness, joy, and sorrow. Commonplace blockheads are not even capable of real joy: they live on in dull insensibility. While to one man his consciousness only presents his own existence, together with the motives which must be apprehended for the purpose of sustaining and enlivening it, in a bare comprehension of the external world, it is to another a camera obscura in which the macrocosm exhibits itself:

"He feels that he holds a little world

Brooding in his brain,
That it begins to work and to live,
That he fain would give it forth."

The difference of the whole manner of existence which the extremes of the gradation of intellectual capacity establish between man and man is so great that that between a king and a day labourer seems small in comparison. And here also, as in the case of the species of animals, a connection between the vehemence of the will and the height of the intellect can be shown. Genius is conditioned by a passionate temperament, and a phlegmatic genius is inconceivable: it seems as if an exceptionally vehement, thus a violently longing, will must be present if nature is to give an abnormally heightened intellect, as corresponding to it; while the merely physical account of this points to the greater energy with which the arteries of the head move the brain and increase its turgescence. Certainly, however, the quantity, quality, and form of the brain itself is the other and incomparably more rare condition of genius. On the other hand, phlegmatic persons are as a rule of very moderate mental power; and thus the northern, cold-blooded, and phlegmatic nations are in general noticeably inferior in mind to the southern vivacious and passionate peoples; although, as Bacon[2] has most pertinently remarked, if once a man of a northern nation is highly gifted by nature, he can then reach a grade which no southern ever attains to. It is accordingly as perverse as it is common to take the great minds of different nations as the standard for comparing their mental powers: for that is just attempting to prove the rule by the exceptions. It is rather the great majority of each nation that one has to consider: for one swallow does not make a summer. We have further to remark here that that very passionateness which is a condition of genius, bound up with its vivid apprehension of things, produces in practical life, where the will comes into play, and especially in the case of sudden occurrences, so great an excitement of the emotions that it disturbs and confuses the intellect; while the phlegmatic man in such a case still retains the full use of his mental faculties, though they are much more limited, and then accomplishes much more with them than the greatest genius can achieve. Accordingly a passionate temperament is favourable to the original quality of the intellect, but a phlegmatic temperament to its use. Therefore genius proper is only for theoretical achievements, for which it can choose and await its time, which will just be the time at which the will is entirely at rest, and no waves

disturb the clear mirror of the comprehension of the world. On the other hand, genius is ill adapted and unserviceable for practical life, and is therefore for the most part unfortunate. Goethe's "Tasso" is written from this point of view. As now genius proper depends upon the absolute strength of the intellect, which must be purchased by a correspondingly excessive vehemence of disposition, so, on the other hand, the great pre-eminence in practical life that makes generals and statesmen depends upon the relative strength of the intellect, thus upon the highest degree of it that can be attained without too great excitability of the emotions, and too great vehemence of character, and that therefore can hold its own even in the storm. Great firmness of will and constancy of mind, together with a capable and fine understanding, are here sufficient; and whatever goes beyond this acts detrimentally, for too great a development of the intelligence directly impedes firmness of character and resolution of will. Hence this kind of eminence is not so abnormal, and is a hundred times less rare than the former kind; and accordingly we see great generals and great ministers appear in every age, whenever the merely external conditions are favourable to their efficiency. Great poets and philosophers, on the other hand, leave centuries waiting for them; and yet humanity may be contented even with this rare appearance of them, for their works remain, and do not exist only for the present, like the achievements of those other men. It is also quite in keeping with the law of the parsimony of nature referred to above that it bestows great eminence of mind in general upon very few, and genius only as the rarest of all exceptions, while it equips the great mass of the human race with no more mental power than is required for the maintenance of the individual and the species. For the great, and through their very satisfaction, constantly increasing needs of the human race make it necessary that the great majority of men should pass their lives in occupations of a coarsely physical and entirely mechanical description. And what would be the use to them of an active mind, a glowing imagination, a subtle understanding, and a profoundly penetrating intellect? These would only make them useless and unhappy. Therefore nature has thus gone about the most costly of all her productions in the least extravagant manner. In order not to judge unfairly one ought also to settle definitely one's expectations of the mental achievements of men generally from this point of view, and to regard, for example, even learned men, since as a rule they have become so only by the force of outward circumstances, primarily as

men whom nature really intended to be tillers of the soil; indeed even professors of philosophy ought to be estimated according to this standard, and then their achievements will be found to come up to all fair expectations. It is worth noticing that in the south, where the necessities of life press less severely upon the human race, and more leisure is allowed, the mental faculties even of the multitude also become more active and finer. It is physiologically noteworthy that the preponderance of the mass of the brain over that of the spinal cord and the nerves, which, according to Sömmerring's acute discovery, affords the true and closest measure of the degree of intelligence both of species of brutes and of individual men, at the same time increases the direct power of moving, the agility of the limbs; because, through the great inequality of the relation, the dependence of all motor nerves upon the brain becomes more decided; and besides this the cerebellum, which is the primary controller of movements, shares the qualitative perfection of the cerebrum; thus through both all voluntary movements gain greater facility, rapidity, and manageableness, and by the concentration of the starting-point of all activity that arises which Lichtenberg praises in Garrick: "that he appeared to be present in all the muscles of his body." Hence clumsiness in the movement of the body indicates clumsiness in the movement of the thoughts, and will be regarded as a sign of stupidity both in individuals and nations, as much as sleepiness of the countenance and vacancy of the glance. Another symptom of the physiological state of the case referred to is the fact that many persons are obliged at once to stand still whenever their conversation with any one who is walking with them begins to gain some connection; because their brain, as soon as it has to link together a few thoughts, has no longer as much power over as is required to keep the limbs in motion by means of the motory nerves, so closely is everything measured with them.

It results from this whole objective consideration of the intellect and its origin, that it is designed for the comprehension of those ends upon the attainment of which depends the individual life and its propagation, but by no means for deciphering the inner nature of things and of the world, which exists independently of the knower. What to the plant is the susceptibility to light, in consequence of which it guides its growth in the direction of it, that is, in kind, the knowledge of the brute, nay, even of man, although in degree it is increased in proportion as the needs of each of these beings demand. With them all apprehension remains a mere consciousness of their

relations to other things, and is by no means intended to present again in the consciousness of the knower the peculiar, absolutely real nature of these things. Rather, as springing from the will, the intellect is also only designed for its service, thus for the apprehension of motives; it is adapted for this, and is therefore of a thoroughly practical tendency. This also holds good if we conceive the significance of life as ethical; for in this regard too we find man knowing only for the benefit of his conduct. Such a faculty of knowledge, existing exclusively for practical ends, will from its nature always comprehend only the relations of things to each other, but not the inner nature of them, as it is in itself. But to regard the complex of these relations as the absolute nature of the world as it is in itself, and the manner in which it necessarily exhibits itself in accordance with the laws predisposed in the brain as the eternal laws of the existence of all things, and then to construct ontology, cosmology, and theology in accordance with this view — this was really the old fundamental error, of which Kant's teaching has made an end. Here, then, our objective, and therefore for the most part physiological consideration of the intellect meets his transcendental consideration of it; nay, appears in a certain sense even as an a priori insight into it; for, from a point of view which we have taken up outside of it, our objective view enables us to know in its origin, and therefore as necessary, what that transcendental consideration, starting from facts of consciousness, presents only as a matter of fact. For it follows from our objective consideration of the intellect, that the world as idea, as it exists stretched out in space and time, and moves on regularly according to the strict law of causality, is primarily only a physiological phenomenon, a function of the brain, which brings it about, certainly upon the occasion of certain external stimuli, but yet in conformity with its own laws. Accordingly it is beforehand a matter of course, that what goes on in this function itself, and therefore through it and for it, must by no means be regarded as the nature of things in themselves, which exist independently of it and are entirely different from it, but primarily exhibits only the mode or manner of this function itself, which can always receive only a very subordinate modification through that which exists completely independently of it, and sets it in motion as a stimulus. As, then, Locke claimed for the organs of sense all that comes into our apprehension by means of the sensation, in order to deny that it belongs to things in themselves, so Kant, with the same intention, and pursuing the same path

further, has proved all that makes perception proper possible, thus space, time, and causality, to be functions of the brain; although he has refrained from using this physiological expression, to which, however, our present method of investigation, coming from the opposite side, the side of the real, necessarily leads us. Kant arrived upon his analytical path at the result that what we know are mere phenomena. What this mysterious expression really means becomes clear from our objective and genetic investigation of the intellect. The phenomena are the motives for the aims of individual will as they exhibit themselves in the intellect which the will has produced for this purpose (which itself appears as a phenomenon objectively, as the brain), and which, when comprehended, as far as one can follow their concatenation, afford us in their connection the world which extends itself objectively in time and space, and which I call the world as idea. Moreover, from our point of view, the objectionable element vanishes which in the Kantian doctrine arises from the fact that, because the intellect knows merely phenomena instead of things as they are in themselves, nay, in consequence of this is led astray into paralogisms and unfounded hypostases by means of "sophistications, not of men but of the reason itself, from which even the wisest does not free himself, and if, perhaps indeed after much trouble, he avoids error, can yet never get quit of the illusion which unceasingly torments and mocks him" — because of all this, I say, the appearance arises that our intellect is intentionally designed to lead us into errors. For the objective view of the intellect given here, which contains a genesis of it, makes it conceivable that, being exclusively intended for practical ends, it is merely the medium of motives, and therefore fulfils its end by an accurate presentation of these, and that if we undertake to discover the nature of things in themselves, from the manifold phenomena which here exhibit themselves objectively to us, and their laws, we do this at our own peril and on our own responsibility. We have recognised that the original inner force of nature, without knowledge and working in the dark, which, if it has worked its way up to self-consciousness, reveals itself to this as will, attains to this grade only by the production of an animal brain and of knowledge, as its function, whereupon the phenomenon of the world of perception arises in this brain. But to explain this mere brain phenomenon, with the conformity to law which is invariably connected with its functions, as the objective inner nature of the world and the things in it, which is independent of the brain, existing before

and after it, is clearly a spring which nothing warrants us in making. From this mundus phœnomenon, however, from this perception which arises under such a variety of conditions, all our conceptions are drawn. They have all their content from it, or even only in relation to it. Therefore, as Kant says, they are only for immanent, not for transcendental, use; that is to say, these conceptions of ours, this first material of thought, and consequently still more the judgments which result from their combination, are unfitted for the task of thinking the nature of things in themselves, and the true connection of the world and existence; indeed, to undertake this is analogous to expressing the stereometrical content of a body in square inches. For our intellect, originally only intended to present to an individual will its paltry aims, comprehends accordingly mere relations of things, and does not penetrate to their inner being, to their real nature. It is therefore a merely superficial force, clings to the surface of things, and apprehends mere species transitivas, not the true being of things. From this it arises that we cannot understand and comprehend any single thing, even the simplest and smallest, through and through, but something remains entirely inexplicable to us in each of them. Just because the intellect is a product of nature, and is therefore only intended for its ends, the Christian mystics have very aptly called it "the light of nature," and driven it back within its limits; for nature is the object to which alone it is the subject. The thought from which the Critique of Pure Reason has sprung really lies already at the foundation of this expression. That we cannot comprehend the world on the direct path, *i.e.*, through the uncritical, direct application of the intellect and its data, but when we reflect upon it become ever more deeply involved in insoluble mysteries, points to the fact that the intellect, thus knowledge itself, is secondary, a mere product, brought about by the development of the inner being of the world, which consequently till then preceded it, and it at last appeared as a breaking through to the light out of the obscure depths of the unconscious striving the nature of which exhibits itself as will to the self-consciousness which now at once arises. That which preceded knowledge as its condition, whereby it first became possible, thus its own basis, cannot be directly comprehended by it; as the eye cannot see itself. It is rather the relations of one existence to another, exhibiting themselves upon the surface of things, which alone are its affair, and are so only by means of the apparatus of the intellect, its forms, space, time, and causality. Just because the world has made itself without the assistance of knowledge,

its whole being does not enter into knowledge, but knowledge presupposes the existence of the world; on which account the origin of the world does not lie within its sphere. It is accordingly limited to the relations between the things which lie before it, and is thus sufficient for the individual will, for the service of which alone it appeared. For the intellect is, as has been shown, conditioned by nature, lies in it, belongs to it, and cannot therefore place itself over against it as something quite foreign to it, in order thus to take up into itself its whole nature, absolutely, objectively, and thoroughly. It can, if fortune favours it, understand all that is in nature, but not nature itself, at least not directly.

However discouraging to metaphysics this essential limitation of the intellect may be, which arises from its nature and origin, it has yet another side which is very consoling. It deprives the direct utterances of nature of their unconditional validity, in the assertion of which naturalism proper consists. If, therefore, nature presents to us every living thing as appearing out of nothing, and, after an ephemeral existence, returning again for ever to nothing, and if it seems to take pleasure in the unceasing production of new beings, in order that it may be able unceasingly to destroy, and, on the other hand, is unable to bring anything permanent to light; if accordingly we are forced to recognise matter as that which alone is permanent, which never came into being and never passes away, but brings forth all things from its womb, whence its name appears to be derived from mater rerum, and along with it, as the father of things, form, which, just as fleeting as matter is permanent, changes really every moment, and can only maintain itself so long as it clings as a parasite to matter (now to one part of it, now to another), but when once it entirely loses hold, disappears, as is shown by the palæotheria and the ichthyosaurians, we must indeed recognise this as the direct and genuine utterance of nature, but on account of the origin of the intellect explained above, and the nature of it which results from this origin, we cannot ascribe to this utterance an unconditional truth, but rather only an entirely conditional truth, which Kant has appropriately indicated as such by calling it the phenomenon in opposition to the thing in itself.

If, in spite of this essential limitation of the intellect, it is possible, by a circuitous route, to arrive at a certain understanding of the world and the nature of things, by means of reflection widely pursued, and the skilful combination of objective knowledge directed towards without, with the data of self-consciousness, this will yet be only a very limited, entirely indirect,

and relative understanding, a parabolical translation into the forms of knowledge, thus a quadam prodire tenus, which must always leave many problems still unsolved. On the other hand, the fundamental error of the old dogmatism in all its forms, which was destroyed by Kant, was this, that it started absolutely from knowledge, i.e., the world as idea, in order to deduce and construct from its laws being in general, whereby it accepted that world of idea, together with its laws, as absolutely existing and absolutely real; while its whole existence is throughout relative, and a mere result or phenomenon of the true being which lies at its foundation, — or, in other words, that it constructed an ontology when it had only materials for a dianoiology. Kant discovered the subjectively conditioned and therefore entirely immanent nature of knowledge, *i.e.*, its unsuitableness for transcendental use, from the constitution of knowledge itself; and therefore he very appropriately called his doctrine the *Critique of Reason*. He accomplished this partly by showing the important and thoroughly a priori part of all knowledge, which, as throughout subjective, spoils all objectivity, and partly by professedly proving that if they were followed out to the end the principles of knowledge, taken as purely objective, led to contradictions. He had, however, hastily assumed that, apart from objective knowledge, *i.e.*, apart from the world as idea, there is nothing given us except conscience, out of which he constructed the little that still remained of metaphysics, his moral theology, to which, however, he attributed absolutely only a practical validity, and no theoretical validity at all. He had overlooked that although certainly objective knowledge, or the world as idea, affords nothing but phenomena, together with their phenomenal connection and regressus, yet our own nature necessarily also belongs to the world of things in themselves, for it must have its root in it. But here, even if the root itself cannot be brought to light, it must be possible to gather some data for the explanation of the connection of the world of phenomena with the inner nature of things. Thus here lies the path upon which I have gone beyond Kant and the limits which he drew, yet always restricting myself to the ground of reflection, and consequently of honesty, and therefore without the vain pretension of intellectual intuition or absolute thought which characterises the period of pseudo-philosophy between Kant and me. In his proof of the insufficiency of rational knowledge to fathom the nature of the world Kant started from knowledge as a fact, which our consciousness affords us, thus in this sense he proceeded a posteriori. But in

this chapter, and also in my work, "*Ueber den Willen in der Natur*," I have sought to show what knowledge is in its nature and origin, something secondary, designed for individual ends; whence it follows that it must be insufficient to fathom the nature of the world. Thus so far I have reached the same goal a priori. But one never knows anything wholly and completely until one has gone right round it for that purpose, and has got back to it from the opposite side from which one started. Therefore also, in the case of the important fundamental knowledge here considered, one must not merely go from the intellect to the knowledge of the world, as Kant has done, but also from the world, taken as given, to the intellect, as I have undertaken here. Then this physiological consideration, in the wider sense, becomes the supplement of that ideological, as the French say, or, more accurately, transcendental consideration.

In the above, in order not to break the thread of the exposition, I have postponed the explanation of one point which I touched upon. It was this, that in proportion as, in the ascending series of animals, the intellect appears ever more developed and complete, knowledge always separates itself more distinctly from will, and thereby becomes purer. What is essential upon this point will be found in my work, "*Ueber den Willen in der Natur*," under the heading, "*Pflanzenphysiologie*" (p. 68-72 of the second, and 74-77 of the third edition), to which I refer, in order to avoid repetition, and merely add here a few remarks. Since the plant possesses neither irritability nor sensibility, but the will objectifies itself in it only as plastic or reproductive power, it has neither muscle nor nerve. In the lowest grades of the animal kingdom, in zoophites, especially in polyps, we cannot as yet distinctly recognise the separation of these two constituent parts, but still we assume their existence, though in a state of fusion; because we perceive movements which follow, not, as in the case of plants, upon mere stimuli, but upon motives, *i.e.*, in consequence of a certain apprehension. Now in proportion as, in the ascending series of animals, the nervous and muscular systems separate ever more distinctly from each other, till in the vertebrate animals, and most completely in man, the former divides into an organic and a cerebral nervous system, and of these the latter again develops into the excessively complicated apparatus of the cerebrum and cerebellum, spinal marrow, cerebral and spinal nerves, sensory and motor nerve fascicles, of which only the cerebrum, together with the sensory nerves depending upon it, and the posterior spinal nerve fascicles are intended for the apprehension

of the motive from the external world, while all the other parts are intended for the transmission of the motive to the muscles in which the will manifests itself directly; in the same proportion does the motive separate ever more distinctly in consciousness from the act of will which it calls forth, thus the idea from the will; and thereby the objectivity of consciousness constantly increases, for the ideas exhibit themselves ever more distinctly and purely in it. These two separations are, however, really only one and the same, which we have here considered from two sides, the objective and the subjective, or first in the consciousness of other things and then in self-consciousness. Upon the degree of this separation ultimately depends the difference and the gradation of intellectual capacity, both between different kinds of animals and between individual human beings; thus it gives the standard for the intellectual completeness of these beings. For the clearness of the consciousness of the external world, the objectivity of the perception, depends upon it. In the passage referred to above I have shown that the brute only perceives things so far as they are motives for its will, and that even the most intelligent of the brutes scarcely overstep these limits, because their intellect is too closely joined to the will from which it has sprung. On the other hand, even the stupidest man comprehends things in some degree objectively; for he recognises not merely what they are with reference to him, but also something of what they are with reference to themselves and to other things. Yet in the case of very few does this reach such a degree that they are in a position to examine and judge of anything purely objectively; but "that must I do, that must I say, that must I believe," is the goal to which on every occasion their thought hastens in a direct line, and at which their understanding at once finds welcome rest. For thinking is as unendurable to the weak head as the lifting of a burden to the weak arm; therefore both hasten to set it down. The objectivity of knowledge, and primarily of perceptive knowledge, has innumerable grades, which depend upon the energy of the intellect and its separation from the will, and the highest of which is genius, in which the comprehension of the external world becomes so pure and objective that to it even more reveals itself directly in the individual thing than the individual thing itself, namely, the nature of its whole species, *i.e.*, its Platonic Idea; which is brought about by the fact that in this case the will entirely vanishes from consciousness. Here is the point at which the present investigation, starting from physiological grounds, connects itself with the subject of our third book, the metaphysics

of the beautiful, where æsthetic comprehension proper, which, in a high degree, is peculiar to genius alone, is fully considered as the condition of pure, *i.e.*, perfectly will-less, and on that account completely objective knowledge. According to what has been said, the rise of intelligence, from the obscurest animal consciousness up to that of man, is a progressive loosening of the intellect from the will, which appears complete, although only as an exception, in the genius. Therefore genius may be defined as the highest grade of the objectivity of knowledge. The condition of this, which so seldom occurs, is a decidedly larger measure of intelligence than is required for the service of the will, which constitutes its basis; it is accordingly this free surplus which first really properly comes to know the world, *i.e.*, comprehends it perfectly objectively, and now paints pictures, composes poems, and thinks in accordance with this comprehension.

Chapter XXIII.[3]On The Objectification Of The Will In Unconscious Nature.

That the will which we find within us does not proceed, as philosophy has hitherto assumed, first from knowledge, and indeed is a mere modification of it, thus something secondary, derived, and, like knowledge itself, conditioned by the brain; but that it is the prius of knowledge, the kernel of our nature, and that original force itself which forms and sustains the animal body, in that it carries out both its unconscious and its conscious functions; — this is the first step in the fundamental knowledge of my metaphysics. Paradoxical as it even now seems to many that the will in itself is without knowledge, yet the scholastics in some way already recognised and confessed it; for Jul. Cæs. Vaninus (that well-known sacrifice to fanaticism and priestly fury), who was thoroughly versed in their philosophy, says in his "*Amphitheatro*," p. 181: "Voluntas potentia cœca est, ex scholasticorum opinione." That, further, it is that same will which in the plant forms the bud in order to develop the leaf and the flower out of it; nay, that the regular form of the crystal is only the trace which its momentary effort has left behind, and that in general, as the true and only αυτοματον, in the proper sense of the word, it lies at the foundation of all the forces of unorganised nature, plays, acts, in all their multifarious phenomena, imparts power to their laws, and even in the crudest mass manifests itself as gravity; — this insight is the second step in that fundamental knowledge, and is brought about by further reflection. But it would be the grossest misunderstanding to suppose that this is a mere question of a word to denote an unknown quantity. It is rather the most real of all real knowledge which is here expressed in language. For it is the tracing back of that which is quite inaccessible to our immediate knowledge, and therefore in its essence foreign and unknown to us, which we denote by the words force of nature, to that which is known to us most accurately and intimately, but which is yet only accessible to us in our own being and directly, and must therefore be carried over from this to other phenomena. It is the insight that what is inward and original in all the changes and movements of bodies, however various they may be, is in its nature identical; that yet we have only one opportunity of getting to know it more closely and directly, and that is in the movements of our own body. In consequence of this knowledge we must

call it will. It is the insight that that which acts and strives in nature, and exhibits itself in ever more perfect phenomena, when it has worked itself up so far that the light of knowledge falls directly upon it, *i.e.*, when it has attained to the state of self-consciousness — exists as that will, which is what is most intimately known to us, and therefore cannot be further explained by anything else, but rather affords the explanation of all other things. It is accordingly the thing in itself so far as this can ever be reached by knowledge. Consequently it is that which must express itself in some way in everything in the world, for it is the inner nature of the world and the kernel of all phenomena.

As my essay, "*Ueber den Willen in der Natur*," specially refers to the subject of this chapter, and also adduces the evidence of unprejudiced empiricists in favour of this important point of my doctrine, I have only to add now to what is said there a few supplementary remarks, which are therefore strung together in a somewhat fragmentary manner.

First, then, with reference to plant life, I draw attention to the remarkable first two chapters of Aristotle's work upon plants. What is most interesting in them, as is so often the case with Aristotle, are the opinions of earlier profound philosophers quoted by him. We see there that Anaxagoras and Empedocles quite rightly taught that plants have the motion of their growth by virtue of their indwelling desires (επιθυμια); nay, that they also attributed to them pleasure and pain, therefore sensation. But Plato only ascribed to them desires, and that on account of their strong appetite for nutrition (*cf.* Plato in the "*Timœus*," p. 403, Bip.) Aristotle, on the other hand, true to his customary method, glides on the surface of things, confines himself to single characteristics and conceptions fixed by current expressions, and asserts that without sensation there can be no desires, and that plants have not sensation. He is, however, in considerable embarrassment, as his confused language shows, till here also, "where fails the comprehension, a word steps promptly in as deputy," namely, το θρεπτικον, the faculty of nourishing. Plants have this, and thus a part of the so-called soul, according to his favourite division into anima vegetativa, sensitiva, and intellectiva. This, however, is just a scholastic Quidditas, and signifies plantœ nutriuntur quia habent facultatem nutritivam. It is therefore a bad substitute for the more profound research of his predecessors, whom he is criticising. We also see, in the second chapter, that Empedocles even recognised the sexuality of

plants; which Aristotle then also finds fault with, and conceals his want of special knowledge behind general propositions, such as this, that plants could not have both sexes combined, for if so they would be more complete than animals. By quite an analogous procedure he displaces the correct astronomical system of the world of the Pythagoreans, and by his absurd fundamental principles, which he specially explains in the books *de Cœlo*, introduces the system of Ptolemy, whereby mankind was again deprived of an already discovered truth of the greatest importance for almost two thousand years.

I cannot refrain from giving here the saying of an excellent biologist of our own time who fully agrees with my teaching. It is G. R. Treviranus, who, in his work, "*Ueber die Erscheinungen und Gesetze des organischen Lebens*," 1832, Bd. 2, Abth. 1, § 49, has said what follows: "A form of life is, however, conceivable in which the effect of the external upon the internal produces merely feelings of desire or dislike. Such is the life of plants. In the higher forms of animal life the external is felt as something objective." Treviranus speaks here from pure unprejudiced comprehension of nature, and is as little conscious of the metaphysical importance of his words as of the contradictio in adjecto which lies in the conception of something "felt as objective," a conception which indeed he works out at great length. He does not know that all feeling is essentially subjective, and all that is objective is, on the other hand, perception, and therefore a product of the understanding. Yet this does not detract at all from the truth and importance of what he says.

In fact, in the life of plants the truth that will can exist without knowledge is apparent — one might say palpably recognisable. For here we see a decided effort, determined by wants, modified in various ways, and adapting itself to the difference of the circumstances, yet clearly without knowledge. And just because the plant is without knowledge it bears its organs of generation ostentatiously in view, in perfect innocence; it knows nothing about it. As soon, on the other hand, as in the series of existences knowledge appears the organs of generation are transferred to a hidden part. Man, however, with whom this is again less the case, conceals them intentionally: he is ashamed of them.

Primarily, then, the vital force is identical with the will, but so also are all other forces of nature; though this is less apparent. If, therefore, we find the recognition of a desire, *i.e.*, of a will, as the basis of plant life,

expressed at all times, with more or less distinctness of conception, on the other hand, the reference of the forces of unorganised nature to the same foundation is rarer in proportion as their remoteness from our own nature is greater. In fact, the boundary between the organised and the unorganised is the most sharply drawn in the whole of nature, and perhaps the only one that admits of no transgressions; so that natura non facit saltus seems to suffer an exception here. Although certain crystallisations display an external form resembling the vegetable, yet even between the smallest lichen, the lowest fungus, and everything unorganised there remains a fundamental and essential difference. In the unorganised body that which is essential and permanent, thus that upon which its identity and integrity rests, is the material, the matter; what is unessential and changing is, on the other hand, the form. With the organised body the case is exactly reversed; for its life, *i.e.*, its existence as an organised being, simply consists in the constant change of the material, while the form remains permanent. Its being and its identity thus lies in the form alone. Therefore the continuance of the unorganised body depends upon repose and exclusion from external influences: thus alone does it retain its existence; and if this condition is perfect, such a body lasts for ever. The continuance of the organised body, on the contrary, just depends upon continual movement and the constant reception of external influences. As soon as these are wanting and the movement in it stops it is dead, and thereby ceases to be organic, although the trace of the organism that has been still remains for a while. Therefore the talk, which is so much affected in our own day, of the life of what is unorganised, indeed of the globe itself, and that it, and also the planetary system, is an organism, is entirely inadmissible. The predicate life belongs only to what is organised. Every organism, however, is throughout organised, is so in all its parts; and nowhere are these, even in their smallest particles, composed by aggregation of what is unorganised. Thus if the earth were an organism, all mountains and rocks, and the whole interior of their mass, would necessarily be organised, and accordingly really nothing unorganised would exist; and therefore the whole conception of it would be wanting.

On the other hand, that the manifestation of a will is as little bound up with life and organisation as with knowledge, and that therefore the unorganised has also a will, the manifestations of which are all its fundamental qualities, which cannot be further explained, — this is an

essential point in my doctrine; although the trace of such a thought is far seldomer found in writers who have preceded me than that of the will in plants, where, however, it is still unconscious.

In the forming of the crystal we see, as it were, a tendency towards an attempt at life, to which, however, it does not attain, because the fluidity of which, like a living thing, it is composed at the moment of that movement is not enclosed in a skin, as is always the case with the latter, and consequently it has neither vessels in which that movement could go on, nor does anything separate it from the external world. Therefore, rigidity at once seizes that momentary movement, of which only the trace remains as the crystal.

The thought that the will, which constitutes the basis of our own nature, is also the same will which shows itself even in the lowest unorganised phenomena, on account of which the conformity to law of both phenomena shows a perfect analogy, lies at the foundation of Goethe's "*Wahlverwandtschaften*," as the title indeed indicates, although he himself was unconscious of this.

Mechanics and astronomy specially show us how this will conducts itself so far as it appears at the lowest grade of its manifestation merely as gravity, rigidity, and inertia. Hydraulics shows us the same thing where rigidity is wanting and the fluid material is now unrestrainedly surrendered to its predominating passion, gravity. In this sense hydraulics may be conceived as a characteristic sketch of water, for it presents to us the manifestations of will to which water is moved by gravity; these always correspond exactly to the external influences, for in the case of all non-individual existences there is no particular character in addition to the general one; thus they can easily be referred to fixed characteristics, which are called laws, and which are learned by experience of water. These laws accurately inform us how water will conduct itself under all different circumstances, on account of its gravity, the unconditioned mobility of its parts, and its want of elasticity. Hydrostatics teaches how it is brought to rest through gravity; hydrodynamics, how it is set in motion; and the latter has also to take account of hindrances which adhesion opposes to the will of water: the two together constitute hydraulics. In the same way Chemistry teaches us how the will conducts itself when the inner qualities of materials obtain free play by being brought into a fluid state, and there appears that wonderful attraction and repulsion, separating and combining, leaving go of

one to seize upon another, from which every precipitation originates, and the whole of which is denoted by “elective affinity” (an expression which is entirely borrowed from the conscious will). But Anatomy and Physiology allow us to see how the will conducts itself in order to bring about the phenomenon of life and sustain it for a while. Finally, the poet shows us how the will conducts itself under the influence of motives and reflection. He exhibits it therefore for the most part in the most perfect of its manifestations, in rational beings, whose character is individual, and whose conduct and suffering he brings before us in the Drama, the Epic, the Romance, &c. The more correctly, the more strictly according to the laws of nature his characters are there presented, the greater is his fame; hence Shakespeare stands at the top. The point of view which is here taken up corresponds at bottom to the spirit in which Goethe followed and loved the natural sciences, although he was not conscious of the matter in the abstract. Nay more, this not only appears from his writings, but is also known to me from his personal utterances.

If we consider the will, where no one denies it, in conscious beings, we find everywhere, as its fundamental effort, the self-preservation of every being: omnis natura vult esse conservatrix sui. But all manifestations of this fundamental effort may constantly be traced back to a seeking or pursuit and a shunning or fleeing from, according to the occasion. Now this also may be shown even at the lowest grades of nature, that is, of the objectification of the will, where the bodies still act only as bodies in general, thus are the subject-matter of mechanics, and are considered only with reference to the manifestations of impenetrability, cohesion, rigidity, elasticity, and gravity. Here also the seeking shows itself as gravitation, and the shunning as the receiving of motion; and the movableness of bodies by pressure or impact, which constitutes the basis of mechanics, is at bottom a manifestation of the effort after self-preservation, which dwells in them also. For, since as bodies they are impenetrable, this is the sole means of preserving their cohesion, thus their continuance at any time. The body which is impelled or exposed to pressure would be crushed to pieces by the impelling or pressing body if it did not withdraw itself from its power by flight, in order to preserve its cohesion; and when flight is impossible for it this actually happens. Indeed, one may regard elastic bodies as the more courageous, which seek to repel the enemy, or at least to prevent him from pursuing further. Thus in the one secret which (besides gravity) is left by

mechanics otherwise so clear, in the communicability of motion, we see a manifestation of the fundamental effort of the will in all its phenomena, the effort after self-preservation, which shows itself even at the lowest grades as that which is essential.

In unorganised nature the will objectifies itself primarily in the universal forces, and only by means of these in the phenomena of the particular things which are called forth by causes. In § 26 of the first volume I have fully explained the relation between cause, force of nature, and will as thing in itself. One sees from that explanation that metaphysics never interrupts the course of physics, but only takes up the thread where physics leaves it, at the original forces in which all causal explanation has its limits. Only here does the metaphysical explanation from the will as the thing in itself begin. In the case of every physical phenomenon, of every change of material things, its cause is primarily to be looked for; and this cause is just such a particular change which has appeared immediately before it. Then, however, the original force of nature is to be sought by virtue of which this cause was capable of acting. And first of all the will is to be recognised as the inner nature of this force in opposition to its manifestation. Yet the will shows itself just as directly in the fall of a stone as in the action of the man; the difference is only that its particular manifestation is in the one case called forth by a motive, in the other by a mechanically acting cause, for example, the taking away of what supported the stone; yet in both cases with equal necessity; and that in the one case it depends upon an individual character, in the other upon an universal force of nature. This identity of what is fundamentally essential is even made palpable to the senses. If, for instance, we carefully observe a body which has lost its equilibrium, and on account of its special form rolls back and forward for a long time till it finds its centre of gravity again, a certain appearance of life forces itself upon us, and we directly feel that something analogous to the foundation of life is also active here. This is certainly the universal force of nature, which, however, in itself identical with the will, becomes here, as it were, the soul of a very brief quasi life. Thus what is identical in the two extremes of the manifestation of the will makes itself faintly known here even to direct perception, in that this raises a feeling in us that here also something entirely original, such as we only know in the acts of our own will, directly succeeded in manifesting itself.

We may attain to an intuitive knowledge of the existence and activity of the will in unorganised nature in quite a different and a sublime manner if we study the problem of the three heavenly bodies, and thus learn more accurately and specially the course of the moon round the earth. By the different combinations which the constant change of the position of these three heavenly bodies towards each other introduces, the course of the moon is now accelerated; now retarded, now it approaches the earth, and again recedes from it; and this again takes place differently in the perihelion of the earth from in its aphelion, all of which together introduces such irregularity into the moon's course that it really obtains a capricious appearance; for, indeed, Kepler's third law is no longer constantly valid, but in equal times it describes unequal areas. The consideration of this course is a small and separate chapter of celestial mechanics, which is distinguished in a sublime manner from terrestrial mechanics by the absence of all impact and pressure, thus of the vis a tergo which appears to us so intelligible, and indeed of the actually completed case, for besides vis inertiœ it knows no other moving and directing force, except only gravitation, that longing for union which proceeds from the very inner nature of bodies. If now we construct for ourselves in imagination the working of this given case in detail, we recognise distinctly and directly in the moving force here that which is given to us in self-consciousness as will. For the alterations in the course of the earth and the moon, according as one of them is by its position more or less exposed to the influence of the sun, are evidently analogous to the influence of newly appearing motives upon our wills, and to the modifications of our action which result.

The following is an illustrative example of another kind. Liebig (*Chemie in Anwendung auf Agrikultur*, p. 501), says: "If we bring moist copper into air which contains carbonic acid, the affinity of the metal for the oxygen of the air will be increased by the contact with this acid to such a degree that the two will combine with each other; its surface will be coated with green carbonic oxide of copper. But now two bodies which have the capacity of combining, the moment they meet assume opposite electrical conditions. Therefore if we touch the copper with iron, by producing a special electrical state, the capacity of the copper to enter into combination with the oxygen is destroyed; even under the above conditions it remains bright." The fact is well known and of technical use. I quote it in order to say that here the will of the copper, laid claim to and occupied by the electrical opposition to iron,

leaves unused the opportunity which presents itself for its chemical affinity for oxygen and carbonic acid. Accordingly it conducts itself exactly as the will in a man who omits an action which he would otherwise feel himself moved to in order to perform another to which a stronger motive urges him.

I have shown in the first volume that the forces of nature lie outside the chain of causes and effects, because they constitute their accompanying condition, their metaphysical foundation, and therefore prove themselves to be eternal and omnipresent, *i.e.*, independent of time and space. Even in the uncontested truth that what is essential to a cause as such consists in this, that it will produce the same effect at any future time as it does now, it is already involved that something lies in the cause which is independent of the course of time, *i.e.*, is outside of all time; this is the force of nature which manifests itself in it. One can even convince oneself to a certain extent empirically and as a matter of fact of the ideality of this form of our perception by fixing one's eyes upon the powerlessness of time as opposed to natural forces. If, for example, a rotatory motion is imparted to a planet by some external cause, if no new cause enters to stop it, this motion will endure for ever. This could not be so if time were something in itself and had an objective, real existence; for then it would necessarily also produce some effect. Thus we see here, on the one hand, the forces of nature, which manifest themselves in that rotation, and, if it is once begun, carry it on for ever without becoming weary or dying out, prove themselves to be eternal or timeless, and consequently absolutely real and existing in themselves; and, on the other hand, time as something which consists only in the manner in which we apprehend that phenomenon, since it exerts no power and no influence upon the phenomenon itself; for what does not act is not.

We have a natural inclination whenever it is possible to explain every natural phenomenon mechanically; doubtless because mechanics calls in the assistance of the fewest original, and hence inexplicable, forces, and, on the other hand, contains much that can be known a priori, and therefore depends upon the forms of our own intellect, which as such carries with it the highest degree of comprehensibility and clearness. However, in the "Metaphysical First Principles of Natural Science" Kant has referred mechanical activity itself to a dynamical activity. On the other hand, the application of mechanical explanatory hypotheses, beyond what is demonstrably mechanical, to which, for example, Acoustics also belongs, is entirely unjustified, and I will never believe that even the simplest chemical

combination or the difference of the three states of aggregation will ever admit of mechanical explanation, much less the properties of light, of heat, and electricity. These will always admit only of a dynamical explanation, *i.e.*, one which explains the phenomenon from original forces which are entirely different from those of impact, pressure, weight, &c., and are therefore of a higher kind, *i.e.*, are more distinct objectifications of that will which obtains visible form in all things. I am of opinion that light is neither an emanation nor a vibration; both views are akin to that which explains transparency from pores and the evident falseness of which is proved by the fact that light is subject to no mechanical laws. In order to obtain direct conviction of this one only requires to watch the effects of a storm of wind, which bends, upsets, and scatters everything, but during which a ray of light shooting down from a break in the clouds is entirely undisturbed and steadier than a rock, so that with great directness it imparts to us the knowledge that it belongs to another order of things than the mechanical: it stands there unmoved like a ghost. Those constructions of light from molecules and atoms which have originated with the French are indeed a revolting absurdity. An article by Ampère, who is otherwise so acute, upon light and heat, which is to be found in the April number of the "*Annales de chimie et physique*," of 1835, may be considered as a flagrant expression of this, and indeed of the whole of atomism in general. There the solid, the fluid, and the elastic consist of the same atoms, and all differences arise solely from their aggregation; nay, it is said that space indeed is infinitely divisible, but not matter; because, if the division has been carried as far as the atoms, the further division must fall in the spaces between the atoms! Light and heat, then, are here vibrations of the atoms; and sound, on the other hand, is a vibration of the molecules composed of the atoms. In truth, however, these atoms are a fixed idea of the French savants, and therefore they just speak of them as if they had seen them. Otherwise one would necessarily marvel that such a matter-of-fact nation as the French can hold so firmly to a completely transcendent hypothesis, which is quite beyond the possibility of experience, and confidently build upon it up to the sky. This is just a consequence of the backward state of the metaphysics they shun so much, which is poorly represented by M. Cousin, who, with all good will, is shallow and very scantily endowed with judgment. At bottom they are still Lockeians, owing to the earlier influence of Condillac. Therefore for them the thing in itself is really matter, from the fundamental

properties of which, such as impenetrability, form, hardness, and the other primary qualities, everything in the world must be ultimately explicable. They will not let themselves be talked out of this, and their tacit assumption is that matter can only be moved by mechanical forces. In Germany Kant's teaching has prevented the continuance of the absurdities of the atomistic and purely mechanical physics for any length of time; although at the present moment these views prevail here also, which is a consequence of the shallowness, crudeness, and folly introduced by Hegel. However, it cannot be denied that not only the evidently porous nature of natural bodies, but also two special doctrines of modern physics, apparently render assistance to the atomic nuisance. These are, Hauz's Crystallography, which traces every crystal back to its kernel form, which is an ultimate form, though only relatively indivisible; and Berzelius's doctrine of chemical atoms, which are yet mere expressions for combining proportions, thus only arithmetical quantities, and at bottom nothing more than counters. On the other hand, Kant's thesis in the second antinomy in defence of atoms, which is certainly only set up for dialectical purposes, is a mere sophism, as I have proved in my criticism of his philosophy, and our understanding itself by no means leads us necessarily to the assumption of atoms. For just as little as I am obliged to think that the slow but constant and uniform motion of a body before my eyes is composed of innumerable motions which are absolutely quick, but broken and interrupted by just as many absolutely short moments of rest, but, on the contrary, know very well that the stone that has been thrown flies more slowly than the projected bullet, yet never pauses for an instant on the way, so little am I obliged to think of the mass of a body as consisting of atoms and the spaces between them, *i.e.*, of absolute density and absolute vacuity; but I comprehend those two phenomena without difficulty as constant continua, one of which uniformly fills time and the other space. But just as the one motion may yet be quicker than another, *i.e.*, in an equal time can pass through more space, so also one body may have a greater specific gravity than another, *i.e.*, in equal space may contain more matter: in both cases the difference depends upon the intensity of the acting force; for Kant (following Priestley) has quite correctly reduced matter to forces. But even if the analogy here set up should not be admitted as valid, and it should be insisted upon that the difference of specific gravity can only have its ground in porosity, even this assumption would always lead, not to atoms, but only to a perfectly dense matter, unequally distributed

among different bodies; a matter which would certainly be no longer compressible, when no pores ran through it, but yet, like the space which it fills, would always remain infinitely divisible. For the fact that it would have no pores by no means involves that no possible force could do away with the continuity of its spatial parts. For to say that everywhere this is only possible by extending the already existing intervals is a purely arbitrary assertion.

The assumption of atoms rests upon the two phenomena which have been touched upon, the difference of the specific gravity of bodies and that of their compressibility, for both are conveniently explained by the assumption of atoms. But then both must also always be present in like measure, which is by no means the case. For, for example, water has a far lower specific gravity than all metals properly so called. It must thus have fewer atoms and greater interstices between them, and consequently be very compressible: but it is almost entirely incompressible.

The defence of atoms might be conducted in this way. One may start from porosity and say something of this sort: All bodies have pores, and therefore so also have all parts of a body: now if this were carried out to infinity, there would ultimately be nothing left of a body but pores. The refutation would be that what remained over would certainly have to be assumed as without pores, and so far as absolutely dense, yet not on that account as consisting of absolutely indivisible particles, atoms; accordingly it would certainly be absolutely incompressible, but not absolutely indivisible. It would therefore be necessary that it should be asserted that the division of a body is only possible by penetrating into its pores; which, however, is entirely unproved. If, however, this is assumed, then we certainly have atoms, *i.e.*, absolutely indivisible bodies, thus bodies of such strong cohesion of their spatial parts that no possible power can separate them: but then one may just as well assume such bodies to be large as small, and an atom might be as big as an ox, if it only would resist all possible attacks upon it.

Imagine two bodies of very different kinds, entirely freed from all pores by compression, as by means of hammering, or by pulverisation; — would their specific gravity then be the same? This would be the criterion of dynamics.

Chapter XXIV. On Matter.

Matter has already been spoken of in the fourth chapter of the supplements to the first book, when we were considering the part of our knowledge of which we are conscious a priori. But it could only be considered there from a one-sided point of view, because we were then concerned merely with its relation to the forms of our intellect, and not to the thing in itself, and therefore we investigated it only from the subjective side, *i.e.*, so far as it is an idea, and not from the objective side, *i.e.*, with regard to what it may be in itself. In the first respect, our conclusion was that it is objective activity in general, yet conceived without fuller determination; therefore it takes the place of causality in the table of our a priori knowledge which is given there. For what is material is that which acts (the actual) in general, and regarded apart from the specific nature of its action. Hence also matter, merely as such, is not an object of perception, but only of thought, and thus is really an abstraction. It only comes into perception in connection with form and quality, as a body, *i.e.*, as a fully determined kind of activity. It is only by abstracting from this fuller determination that we think of matter as such, *i.e.*, separated from form and quality; consequently under matter we think of acting absolutely and in general, thus of activity in the abstract. The more fully determined acting we then conceive as the accident of matter; but only by means of this does matter become perceptible, *i.e.*, present itself as a body and an object of experience. Pure matter, on the other hand, which, as I have shown in the Criticism of the Kantian Philosophy, alone constitutes the true and admissible content of the conception of substance, is causality itself, thought objectively, consequently as in space, and therefore filling it. Accordingly the whole being of matter consists in acting. Only thus does it occupy space and last in time. It is through and through pure causality. Therefore wherever there is action there is matter, and the material is the active in general. But causality itself is the form of our understanding; for it is known to us a priori, as well as time and space. Thus matter also, so far and up to this point, belongs to the formal part of our knowledge, and is consequently that form of the understanding, causality itself, bound up with space and time, hence objectified, *i.e.*, conceived as that which fills space. (The fuller explanation of this doctrine will be found in the second edition of the essay on the principle of sufficient reason, p. 77;

third edition, p. 82.) So far, however, matter is properly not the object but the condition of experience; like the pure understanding itself, whose function it so far is. Therefore of pure matter there is also only a conception, no perception. It enters into all external experience as a necessary constituent part of it; yet it cannot be given in any experience, but is only thought, and thought indeed as that which is absolutely inert, inactive, formless, and without qualities, and which is yet the supporter of all forms, qualities, and effects. Accordingly, of all fleeting phenomena, thus of all manifestations of natural forces and all living beings, matter is the permanent substratum which is necessarily produced by the forms of our intellect in which the world as idea exhibits itself. As such, and as having sprung from the forms of the intellect, it is entirely indifferent to those phenomena themselves, *i.e.*, it is just as ready to be the supporter of this force of nature as of that, whenever, under the guidance of causality, the necessary conditions appear; while it itself, just because its existence is really only formal, *i.e.*, is founded in the intellect must be thought as that which under all that change is absolutely permanent, thus with regard to time is without beginning and without end. This is why we cannot give up the thought that anything may be made out of anything, for example, gold out of lead; for this would only require that we should find out and bring about the intermediate states which matter, in itself indifferent, would have to pass through upon that path. For a priori we can never see why the same matter which is now the supporter of the quality lead could not some time become the supporter of the quality gold. Matter, as that which is only thought a priori, is distinguished from the a priori intuitions or perceptions proper by the fact that we can also think it entirely away; space and time, on the contrary, never. But this only shows that we can present to ourselves space and time in imagination without matter. For the matter which has once been placed in them, and accordingly thought as existing, we can never again absolutely think away, *i.e.*, imagine it as vanished and annihilated, but are always forced to think of it merely as transferred to another space. So far, then, matter is as inseparably connected with our faculty of knowledge as space and time themselves. Yet even the difference that it must first be voluntarily thought as existing indicates that it does not belong so entirely and in every regard to the formal part of our knowledge as space and time, but also contains an element which is only given a posteriori. It is, in fact, the point of connection of the empirical part of our

knowledge with the pure and a priori part, consequently the peculiar foundation-stone of the world of experience.

Only where all a priori assertions cease, therefore in the entirely empirical part of our knowledge of bodies, in their form, quality, and definite manner of acting, does that will reveal itself which we have already recognised and established as the true inner nature of things. But these forms and qualities always appear only as the properties and manifestations of that very matter the existence and nature of which depends upon the subjective forms of our intellect, i.e., they only become visible in it, and therefore by means of it. For that which always exhibits itself to us is only matter acting in some specially determined manner. Out of the inner properties of such matter, properties which cannot be further explained, proceeds every definite kind of effect of given bodies; and yet the matter itself is never perceived, but only these effects, and the definite properties which lie at their foundation, after separating which, matter, as that which then remains over, is necessarily added in thought by us; for, according to the exposition given above, it is objectified causality itself. Accordingly matter is that whereby the will, which constitutes the inner nature of things, becomes capable of being apprehended, perceptible, visible. In this sense, then, matter is simply the visibility of the will, or the bond between the world as will and the world as idea. It belongs to the latter inasmuch as it is the product of the functions of the intellect, to the former inasmuch as that which manifests itself in all material existences, i.e., phenomena is the will. Therefore every object is, as thing in itself, will, and as phenomenon, matter. If we could strip any given matter of all the properties that come to it a priori, i.e., of all the forms of our perception and apprehension, we would have left the thing in itself, that which, by means of those forms, appears as the purely empirical in matter, but which would then itself no longer appear as something extended and active; i.e., we would no longer have matter before us, but the will. This very thing in itself, or the will, in that it becomes a phenomenon, i.e., enters the forms of our intellect, appears as matter, i.e., as the invisible but necessarily assumed supporter of the properties which are only visible through it. In this sense, then, matter is the visibility of the will. Consequently Plotinus and Giordano Bruno were right, not only in their sense but also in ours, when they made the paradoxical assertion already referred to in chapter 4: Matter itself is not extended, consequently it is incorporeal. For space, which is our form of

perception, imparts extension to matter, and corporeal existence consists in acting, which depends upon causality, and consequently upon the form of our understanding. On the other hand, every definite property, thus everything empirical in matter, even gravity, depends upon that which only becomes visible by means of matter, the thing in itself, the will. Gravity is yet the lowest of all grades of the objectification of the will; therefore it appears in all matter without exception, thus is inseparable from matter in general. Yet, just because it is a manifestation of the will, it belongs to knowledge a posteriori, not to knowledge a priori. Therefore we can always picture to ourselves matter without weight, but not without extension, repulsive force, and stability, for then it would be without impenetrability, and consequently would not occupy space, *i.e.*, it would be without the power of acting; but the nature of matter as such just consists in acting, *i.e.*, in causality in general; and causality depends upon the a priori form of our understanding, and therefore cannot be thought away.

Matter is accordingly the will itself, but no longer in itself, but so far as it is perceived, *i.e.*, assumes the form of the objective idea. Thus what objectively is matter is subjectively will. Exactly corresponding to this, as was proved above, our body is just the visibility, objectivity of our will, and so also every body is the objectivity of the will at some one of its grades. Whenever the will exhibits itself to objective knowledge it enters into the forms of perception of the intellect, time, space, and causality. But on account of this it exists at once as a material object. We can present to our minds form without matter, but not the reverse; because matter deprived of form would be the will itself, and the will only becomes objective by entering the forms of perception of our intellect, and therefore only by means of the assumption of form. Space is the form of perception of matter because the latter is the substance (Stoff) of mere form, but matter can appear only in form.

Since the will becomes objective, *i.e.*, passes over into the idea, matter is the universal substratum of this objectification, or rather it is this objectification itself taken abstractly, *i.e.*, regarded apart from all form. Matter is accordingly the visibility of the will in general, while the character of its definite manifestations has its expression in form and quality. Hence what in the manifestation, *i.e.*, for the idea, is matter is in itself will. Therefore, under the conditions of experience and perception, everything holds good of it that holds good of the will in itself, and it repeats all the

relations and properties of the will in temporal images. Accordingly it is the substance of the world of perception, as the will is the inner nature of all things. The forms are innumerable, the matter is one; just as the will is one in all its objectifications. As the will never objectifies itself as general, *i.e.*, as absolute will, but always as particular, *i.e.*, under special determinations and a given character, so matter never appears as such, but always in connection with some particular form and quality. In the manifestation or objectification of the will matter represents its totality, it itself, which in all is one, as matter is one in all bodies. As the will is the inmost kernel of all phenomenal beings, so matter is the substance which remains after all the accidents have been taken away. As the will is that which is absolutely indestructible in all existence, so matter is that which is imperishable in time and permanent through all changes. That matter for itself, thus separated from form, cannot be perceived or presented in imagination depends upon the fact that in itself, and as the pure substantiality of bodies, it is really the will itself. But the will cannot be apprehended objectively, or perceived in itself, but only under all the conditions of the idea, and therefore only as phenomenon. Under these conditions, however, it exhibits itself at once as body, *i.e.*, as matter clothed in form and quality. But form is conditioned by space, and quality or power of acting by causality; thus both depend upon the functions of the intellect. Matter without them would just be the thing in itself, *i.e.*, the will itself. Therefore, as has been said, Plotinus and Giordano Bruno could only be brought by a completely objective path to the assertion that matter in and for itself is without extension, consequently without spatial properties, consequently incorporeal.

Because, then, matter is the visibility of the will, and every force in itself is will, no force can appear without a material substratum, and conversely no body can be without forces dwelling in it which constitute its quality. Therefore a body is the union of matter and form which is called substance (Stoff). Force and substance are inseparable because at bottom they are one; for, as Kant has shown, matter itself is given us only as the union of two forces, the force of expansion and that of attraction. Thus there is no opposition between force and substance, rather they are precisely one.

Led by the course of our consideration to this standpoint, and having attained to this metaphysical view of matter, we will confess without reluctance that the temporal origin of forms, shapes, or species cannot

reasonably be sought elsewhere than in matter. Some time or other they must have come forth from it, just because it is the mere visibility of the will which constitutes the inner nature of all phenomena. In that the will manifests itself, *i.e.*, presents itself objectively to the intellect, matter, as its visibility, assumes form by means of the functions of the intellect. Hence the Schoolmen said: "Materia appetit formam." That such was the origin of all forms of life cannot be doubted: we cannot even conceive it otherwise. Whether, however, now, since the paths to the perpetuation of the forms stand open, and are secured and sustained by nature with boundless care and jealousy, generatio œquivoca still takes place, can only be decided by experience; especially since the saying, Natura nihil facit frustra, might, with reference to the paths of regular propagation, be used as a valid argument against it. Yet in spite of the most recent objections to it, I hold that at very low grades generatio œquivoca is very probable, and primarily indeed in the case of entozoa and epizoa, particularly such as appear in consequence of special cachexia of the animal organism. For the conditions of their life only appear exceptionally; consequently their species cannot propagate itself in the regular manner, and therefore has always to arise anew whenever opportunity offers. Therefore as soon as the conditions of life of epizoa have appeared in consequence of certain chronic diseases, or cachexia, and in accordance with them, pediculus capitis or pubis or corporis appears entirely of itself, and without any egg; and this notwithstanding the complex structure of these insects, for the putrefaction of a living animal body affords material for higher productions than that of hay in water, which only produces infusoria. Or is it thought more likely that the eggs of the epizoa are constantly floating about in the air in expectation? (Fearful to think of!) Let us rather remember the disease of phthiriasis, which occurs even now. An analogous case takes place when through special circumstances the conditions of life appear of a species which up till then was foreign to that place. Thus August St. Hilaire saw in Brazil, after the burning of a primitive forest, as soon as ever the ashes had cooled, a number of plants grow up out of them, the species of which was not to be found far and wide; and quite recently Admiral Petit-Thouars informed the *Académie des sciences* that upon the growing coral islands in Polynesia a soil gradually deposits itself which is now dry, now lies in water, and which vegetation soon takes possession of, bringing forth trees which are absolutely peculiar to these islands (*Comptes rendus*, 17th Jan.

1859, p. 147). Whenever putrefaction takes place mould, fungi, and in liquids infusoria appear. The assumption now in favour that spores and eggs of the innumerable species of all those kinds of animal life are everywhere floating in the air, and wait through long years for a favourable opportunity, is more paradoxical than that of generatio œquivoca. Putrefaction is the decomposition of an organised body, first into its more immediate chemical constituents. Since now these are more or less the same in all living beings, the omnipresent will to live can possess itself of them, in order, in accordance with the circumstances, to produce new existences from them; and these forming themselves according to design, *i.e.*, objectifying the volition of the will at the time, solidify out of the chemical elements as the chicken out of the fluidity of the egg. When, however, this does not take place, the putrefying matter is resolved into its ultimate constituent parts, which are the chemical elements, and now passes over again into the great course of nature. The war which has been waged for the last ten or fifteen years against generatio œquivoca, with its premature shouts of victory, was the prelude to the denial of the vital force, and related to it. Let no one, however, be deceived by dogmatic assertions and brazen assurances that the questions are decided, settled, and generally recognised. On the contrary, the whole mechanical and atomistic view of nature is approaching its bankruptcy, and its defenders have to learn that something more is concealed behind nature than action and reaction. The reality of generatio œquivoca and the folly of the extraordinary assumption that in the atmosphere, everywhere and always, billions of seeds of all possible kinds of fungi, and eggs of all possible kinds of infusoria, are floating about, till now one and then another by chance finds its suitable medium, has quite recently (1859) been thoroughly and victoriously shown by Pouchet before the French Academy, to the great vexation of the other members.

Our wonder at the origin of forms in matter is at bottom like that of the savage who looks for the first time in a mirror and marvels at his own image which he sees there. For our own inner nature is the will, whose mere visibility is matter. Yet matter never appears otherwise than with the visible, *i.e.*, under the outer shell of form and quality, and therefore is never directly apprehended, but always merely added in thought as that which is identical in all things, under all differences of quality and form. On this account it is more a metaphysical than a physical principle of explanation of things, and to make all existences arise from it is really to explain them from something

which is very mysterious; which all know it to be except those who confound attacking with comprehending. In truth, the ultimate and exhaustive explanation of things is by no means to be sought in matter, although certainly the temporal origin both of unorganised forms and of organised beings is to be sought in it. Yet it seems that the origination of organised forms, the production of the species themselves, is almost as difficult for nature to accomplish as it is for us to comprehend. This is indicated by the entirely extravagant provision which nature always makes for maintaining the species which once exist. Yet on the present surface of this planet the will to live has gone through the scale of its objectification three times, quite independently of each other, in a different modulation, and also with great difference of perfection and fulness. The old world, America, and Australia have, it is well known, each their peculiar independent fauna, entirely different from that of the other two. Upon each of these great continents the species are throughout different, but yet, because all three belong to the same planet, they have a thorough analogy with each other running parallel through them; therefore the genera are for the most part the same. In Australia this analogy can only be very imperfectly followed because its fauna is very poor in mammalia, and contains neither beasts of prey nor apes. On the other hand, between the old world and America it is obvious, and in the following manner. In mammals America always produces the inferior analogue, but in birds and reptiles the better. Thus it has the advantage in the condor, the macaw, the humming-bird, and the largest batrachia and ophidia; but, for example, instead of the elephant it has only the tapir, instead of the lion the puma, instead of the tiger the jaguar, instead of the camel the lama, and instead of apes proper only monkeys. Even from this last defect it may be concluded that in America nature was not able to rise to man; for even from the nearest grade below man, the chimpanzee and the orang-outang or pongo, the step to man was still an excessively great one. Correspondingly we find that the three races of men which, both upon physiological and linguistic grounds, are undoubtedly equally original, the Caucasian, the Mongolian, and the Ethiopian, are only at home in the old world; while America, on the other hand, is peopled by a mixed or climatically modified Mongolian race, which must have come over from Asia. On the surface of the earth which immediately preceded the present surface apes were reached here and there, but not men.

From this standpoint of our consideration, which shows us matter as the direct visibility of the will which manifests itself in all things, nay, indeed, for the merely physical investigation which follows the guidance of time and causality, lets it pass as the origin of things, we are easily led to the question whether even in philosophy we could not just as well start from the objective as from the subjective side, and accordingly set up as the fundamental truth the proposition: “There is in general nothing but matter and its indwelling forces.” But, with regard to these “indwelling forces” here so easily used, we must remember that their assumption leads every explanation back to a completely incomprehensible miracle, and then leaves it beside it, or rather leaves it to begin from it. For every definite, inexplicable force of nature which lies at the foundation of the most different kinds of effects of an unorganised body, not less than the vital force which manifests itself in every organised body, is such an incomprehensible miracle, as I have fully explained in chap. 17, and have also shown that physics can never be set upon the throne of metaphysics, just because it leaves quite untouched the assumption referred to and also many others; whereby from the beginning it renounces all claim to give an ultimate explanation of things. I must further remind the reader here of the proof of the insufficiency of materialism, which is given towards the end of the first chapter, because, as was said there, it is the philosophy of the subject which forgets itself in its calculation. But all these truths rest upon the fact that everything objective, everything external, since it is always only something apprehended, something known, remains also always indirect and secondary, therefore absolutely never can become the ultimate ground of explanation of things or the starting-point of philosophy. Philosophy necessarily requires what is absolutely immediate for its starting-point. But clearly only that which is given in self-consciousness fulfils this condition, that which is within, the subjective. And hence it is so eminent a merit of Descartes that he first made philosophy start from self-consciousness. Since then, upon this path, the genuine philosophers, especially Locke, Berkeley, and Kant, have gone even further, each in his own manner, and in consequence of their investigations I was led to recognise and make use, not of one, but of two completely different data of immediate knowledge in self-consciousness, the idea and the will, by the combined application of which one can go further in philosophy, in the same proportion as in the case of an algebraical problem one can

accomplish more if two known quantities are given than if only one is given.

In accordance with what has been said, the ineradicable falseness of materialism primarily consists in the fact that it starts from a petitio principii, which when more closely considered turns out indeed to be a πρωτον φευδος. It starts from the assumption that matter is something absolutely and unconditionally given, something existing independently of the knowledge of the subject, thus really a thing in itself. It attributes to matter (and consequently also to its presuppositions time and space) an absolute existence, *i.e.*, an existence independent of the perceiving subject; this is its fundamental error. Then, if it will go honestly to work, it must leave the qualities inherent in the given materials, *i.e.*, in the substances, together with the natural forces which manifest themselves in these, and finally also the vital force, unexplained, as unfathomable qualitates occultæ, and start from them; as physics and physiology actually do, because they make no claim to be the ultimate explanation of things. But just to avoid this, materialism — at least as it has hitherto appeared — has not proceeded honestly. It denies all those original forces, for it pretends and seems to reduce them all, and ultimately also the vital force, to the mere mechanical activity of matter, thus to manifestations of impenetrability, form, cohesion, impulsive power, inertia, gravity, &c., qualities which certainly have least that is inexplicable in themselves, just because they partly depend upon what is known a priori, consequently on the forms of our own intellect, which are the principle of all comprehensibility. But the intellect as the condition of all objects, and consequently of the whole phenomenal world, is entirely ignored by materialism. Its plan is now to refer everything qualitative to something merely quantitative, for it attributes the former to mere form in opposition to matter proper. To matter it leaves, of the properly empirical qualities, only gravity, because it already appears as something quantitative, the only measure of the quantity of the matter. This path necessarily leads it to the fiction of atoms, which now become the material out of which it thinks to construct the mysterious manifestations of all original forces. But here it has really no longer to do with empirically given matter, but with a matter which is not to be found in rerum natura, but is rather a mere abstraction of that real matter, a matter which would absolutely have no other than those mechanical qualities which, with the

exception of gravity, can be pretty well construed a priori, just because they depend upon the forms of space, time, and causality, and consequently upon our intellect; to this poor material, then, it finds itself reduced for the construction of its castle in the air.

In this way it inevitably becomes atomism; as happened to it already in its childhood in the hands of Leucippus and Democritus, and happens to it again now that it has come to a second childhood through age; with the French because they have never known the Kantian philosophy, and with the Germans because they have forgotten it. And indeed it carries it further in this its second childhood than in its first. Not merely solid bodies are supposed to consist of atoms, but liquids, water, air, gas, nay, even light, which is supposed to be the undulations of a completely hypothetical and altogether unproved ether, consisting of atoms, the difference of the rapidity of these undulations causing colours. This is an hypothesis which, like the earlier Newtonian seven-colour theory, starts from an analogy with music, entirely arbitrarily assumed, and then violently carried out. One must really be credulous to an unheard-of degree to let oneself be persuaded that the innumerable different ether vibrations proceeding from the infinite multiplicity of coloured surfaces in this varied world could constantly, and each in its own time, run through and everywhere cross each other without ever disturbing each other, but should rather produce through such tumult and confusion the profoundly peaceful aspect of illumined nature and art. Credat Judæus Apella! Certainly the nature of light is to us a secret; but it is better to confess this than to bar the way of future knowledge by bad theories. That light is something quite different from a mere mechanical movement, undulation, or vibration and tremor, indeed that it is material, is shown by its chemical effects, a beautiful series of which was recently laid before the *Académie des sciences* by Chevreul, who let sunlight act upon different coloured materials. The most beautiful thing in these experiments is, that a white roll of paper which has been exposed to the sunlight exhibits the same effects, nay, does so even after six months, if during this time it has been secured in a firmly closed metal tube. Has, then, the tremulation paused for six months, and does it now fall into time again? (*Comptes rendus* of 20th December 1858.) This whole hypothesis of vibrating ether atoms is not only a chimera, but equals in awkward crudeness the worst of Democritus, and yet is shameless enough, at the present day, to profess to be an established fact, and has thus brought it about that it is orthodoxly

repeated by a thousand stupid scribblers of all kinds, who are devoid of all knowledge of such things, and is believed in as a gospel. But the doctrine of atoms in general goes still further: it is soon a case of Spartam, quam nactus es, orna! Different perpetual motions are then ascribed to all the atoms, revolving, vibrating, &c., according to the office of each; in the same way every atom has its atmosphere of ether, or something else, and whatever other similar fancies there may be. The fancies of Schelling's philosophy of nature and its disciples were for the most part ingenious, lofty, or at least witty; but these, on the contrary, are clumsy, insipid, paltry, and awkward, the production of minds which, in the first place, are unable to think any other reality than a fabulous, qualityless matter, which is also an absolute object, *i.e.*, an object without a subject; and secondly can think of no other activity than motion and impact: these two alone are comprehensible to them, and that everything runs back to these is their a priori assumption; for these are their thing in itself. To attain this end the vital force is reduced to chemical forces (which are insidiously and unjustifiably called molecular forces), and all processes of unorganised nature to mechanism, *i.e.*, to action and reaction. And thus at last the whole world and everything in it becomes merely a piece of mechanical ingenuity, like the toys worked by levers, wheels, and sand, which represent a mine or the work on a farm. The source of the evil is, that through the amount of hand-work which experimenting requires the head-work of thinking has been allowed to get out of practice. The crucible and the voltaic pile are supposed to assume its functions; hence also the profound abhorrence of all philosophy.

But the matter might be put in this way. One might say that materialism, as it has hitherto appeared, has only failed because it did not adequately know the matter out of which it thought to construct the world, and therefore was dealing, not with matter itself, but with a propertyless substitute for it. If, on the contrary, instead of this, it had taken the actual and empirically given matter (*i.e.*, material substance, or rather substances), endowed as it is with all physical, chemical, electrical properties, and also with the power of spontaneously producing life out of itself, thus the true mater rerum, from the obscurity of whose womb all phenomena and forms come forth, to fall back into it some time again; from this, *i.e.*, from matter fully comprehended and exhaustively known, a world might have been constructed of which materialism would not need to be ashamed. Quite true: only the trick would then consist in this, that the Quæsita had been placed in

the Data, for professedly what was taken as given, and made the starting-point of the deduction, was mere matter, but really it included all the mysterious forces of nature which cling to it, or more correctly, by means of it become visible to us, much the same as if under the name of the dish we understand what lies upon it. For in fact, for our knowledge, matter is really merely the vehicle of the qualities and natural forces, which appear as its accidents, and just because I have traced these back to the will I call matter the mere visibility of the will. Stripped of all these qualities, matter remains behind as that which is without qualities, the caput mortuum of nature, out of which nothing can honestly be made. If, on the contrary, in the manner referred to, one leaves it all these properties, one is guilty of a concealed petitio principii, for one has assumed the Quæsita beforehand as Data. But what is accomplished with this will no longer be a proper materialism, but merely naturalism, *i.e.*, an absolute system of physics, which, as was shown in chap. 17 already referred to, can never assume and fill the place of metaphysics, just because it only begins after so many assumptions, thus never undertakes to explain things from the foundation. Mere naturalism is therefore essentially based simply upon qualitates occultæ, which one can never get beyond except, as I have done, by calling in the aid of the subjective source of knowledge, which then certainly leads to the long and toilsome round-about path of metaphysics, for it presupposes the complete analysis of self-consciousness and of the intellect and will given in it. However, the starting from what is objective, at the foundation of which lies external perception, so distinct and comprehensible, is a path so natural and which presents itself of its own accord to man, that naturalism, and consequently, because this cannot satisfy as it is not exhaustive, materialism, are systems to which the speculative reason must necessarily have come, nay, must have come first of all. Therefore at the very beginning of the history of philosophy we meet naturalism, in the systems of the Ionic philosophers, and then materialism in the teaching of Leucippus and Democritus, and also later we see them ever appear anew from time to time.

Chapter XXV. Transcendent Considerations Concerning The Will As Thing In Itself.

Even the merely empirical consideration of nature recognises a constant transition from the simplest and most necessary manifestation of a universal force of nature up to the life and consciousness of man himself, through gentle gradations, and with only relative, and for the most part fluctuating, limits. Reflection, following this view, and penetrating somewhat more deeply into it, will soon be led to the conviction that in all these phenomena, the inner nature, that which manifests itself, that which appears, is one and the same, which comes forth ever more distinctly; and accordingly that what exhibits itself in a million forms of infinite diversity, and so carries on the most varied and the strangest play without beginning or end, this is one being which is so closely disguised behind all these masks that it does not even recognise itself, and therefore often treats itself roughly. Thus the great doctrine of the ἐν και παν early appeared both in the east and in the west, and, in spite of all contradiction, has asserted itself, or at least constantly revived. We, however, have now entered even deeper into the secret, since by what has already been said we have been led to the insight that when in any phenomenon a knowing consciousness is added to that inner being which lies at the foundation of all phenomena, a consciousness which when directed inwardly becomes self-consciousness, then that inner being presents itself to this self-consciousness as that which is so familiar and so mysterious, and is denoted by the word will. Accordingly we have called that universal fundamental nature of all phenomena the will, after that manifestation in which it unveils itself to us most fully; and by this word nothing is further from our intention than to denote an unknown x; but, on the contrary, we denote that which at least on one side is infinitely better known and more intimate than anything else.

Let us now call to mind a truth, the fullest and most thorough proof of which will be found in my prize essay on the freedom of the will — the truth that on account of the absolutely universal validity of the law of causality, the conduct or the action of all existences in this world is always strictly necessitated by the causes which in each case call it forth. And in this respect it makes no difference whether such an action has been occasioned by causes in the strictest sense of the word, or by stimuli, or

finally by motives, for these differences refer only to the grade of the susceptibility of the different kinds of existences. On this point we must entertain no illusion: the law of causality knows no exception; but everything, from the movement of a mote in a sunbeam to the most deeply considered action of man, is subject to it with equal strictness. Therefore, in the whole course of the world, neither could a mote in a sunbeam describe any other line in its flight than it has described, nor a man act any other way than he has acted; and no truth is more certain than this, that all that happens, be it small or great, happens with absolute necessity. Consequently, at every given moment of time, the whole condition of all things is firmly and accurately determined by the condition which has just preceded it, and so is it with the stream of time back to infinity and on to infinity. Thus the course of the world is like that of a clock after it has been put together and wound up; thus from this incontestable point of view it is a mere machine, the aim of which we cannot see. Even if, quite without justification, nay, at bottom, in spite of all conceivability and its conformity to law, one should assume a first beginning, nothing would thereby be essentially changed. For the arbitrarily assumed first condition of things would at its origin have irrevocably determined and fixed, both as a whole and down to the smallest detail, the state immediately following it; this state, again, would have determined the one succeeding it, and so on per secula seculorum, for the chain of causality, with its absolute strictness — this brazen bond of necessity and fate — introduces every phenomenon irrevocably and unalterably, just as it is. The difference merely amounts to this, that in the case of the one assumption we would have before us a piece of clockwork which had once been wound up, but in the case of the other a perpetual motion; the necessity of the course, on the other hand, would remain the same. In the prize essay already referred to I have irrefutably proved that the action of man can make no exception here, for I showed how it constantly proceeds with strict necessity from two factors — his character and the motives which come to him. The character is inborn and unalterable; the motives are introduced with necessity under the guidance of causality by the strictly determined course of the world.

Accordingly then, from one point of view, which we certainly cannot abandon, because it is established by the objective laws of the world, which are a priori valid, the world, with all that is in it, appears as an aimless, and therefore incomprehensible, play of an eternal necessity, an inscrutable and

inexorable Αναγκη. Now, what is objectionable, nay, revolting, in this inevitable and irrefutable view of the world cannot be thoroughly done away with by any assumption except this, that as in one aspect every being in the world is a phenomenon, and necessarily determined by the laws of the phenomenon, in another aspect it is in itself will, and indeed absolutely free will, for necessity only arises through the forms which belong entirely to the phenomenon, through the principle of sufficient reason in its different modes. Such a will, then, must be self-dependent, for, as free, *i.e.*, as a thing in itself, and therefore not subject to the principle of sufficient reason, it cannot depend upon another in its being and nature any more than in its conduct and action. By this assumption alone will as much freedom be supposed as is needed to counterbalance the inevitable strict necessity which governs the course of the world. Accordingly one has really only the choice either of seeing that the world is a mere machine which runs on of necessity, or of recognising a free will as its inner being whose manifestation is not directly the action but primarily the existence and nature of things. This freedom is therefore transcendental, and consists with empirical necessity, in the same way as the transcendental ideality of phenomena consists with their empirical reality. That only under this assumption the action of a man, in spite of the necessity with which it proceeds from his character and the motives, is yet his own I have shown in my prize essay on the freedom of the will; with this, however, self-dependency is attributed to his nature. The same relation holds good of all things in the world. The strictest necessity, carried out honestly with rigid consistency, and the most perfect freedom, rising to omnipotence, had to appear at once and together in philosophy; but, without doing violence to truth, this could only take place by placing the whole necessity in the acting and doing (Operari), and the whole freedom in the being and nature (Esse). Thereby a riddle is solved which is as old as the world, simply because it has hitherto always been held upside down and the freedom persistently sought in the Operari, the necessity in the Esse. I, on the contrary, say: Every being without exception acts with strict necessity, but it exists and is what it is by virtue of its freedom. Thus with me freedom and necessity are to be met with neither more nor less than in any earlier system; although now one and now the other must be conspicuous according as one takes offence that will is attributed to processes of nature which hitherto were explained from necessity, or that the same strict necessity is recognised in

motivation as in mechanical causality. The two have merely changed places: freedom has been transferred to the Esse, and necessity limited to the Operari.

In short, Determinism stands firm. For fifteen hundred years men have wearied themselves in vain to shake it, influenced by certain crotchets, which are well known, but dare scarcely yet be called by their name. Yet in accordance with it the world becomes a mere puppet-show, drawn by wires (motives), without it being even possible to understand for whose amusement. If the piece has a plan, then fate is the director; if it has none, then blind necessity. There is no other deliverance from this absurdity than the knowledge that the being and nature of all things is the manifestation of a really free will, which knows itself in them; for their doing and acting cannot be delivered from necessity. To save freedom from fate and chance, it had to be transferred from the action to the existence.

As now necessity only affects the phenomenon, not the thing in itself, *i.e.*, the true nature of the world, so also does multiplicity. This is sufficiently explained in § 25 of the first volume. I have only to add here one remark in confirmation and illustration of this truth.

Every one knows only one being quite immediately — his own will in self-consciousness. Everything else he knows only indirectly, and then judges it by analogy with this; a process which he carries further in proportion to the grade of his reflective powers. Even this ultimately springs from the fact that there really is only one being; the illusion of multiplicity (Maja), which proceeds from the forms of external, objective comprehension, could not penetrate to inner, simple consciousness; therefore this always finds before it only one being.

If we consider the perfection of the works of nature, which can never be sufficiently admired, and which even in the lowest and smallest organisms, for example, in the fertilising parts of plants or in the internal construction of insects, is carried out with as infinite care and unwearied labour as if each work of nature had been its only one, upon which it was therefore able to expend all its art and power; if we yet find this repeated an infinite number of times in each one of innumerable individuals of every kind, and not less carefully worked out in that one whose dwelling-place is the most lonely, neglected spot, to which, till then, no eye had penetrated; if we now follow the combination of the parts of every organism as far as we can, and yet never come upon one part which is quite simple, and therefore ultimate,

not to speak of one which is inorganic; if, finally, we lose ourselves in calculating the design of all those parts of the organism for the maintenance of the whole by virtue of which every living thing is complete in and for itself; if we consider at the same time that each of these masterpieces, itself of short duration, has already been produced anew an innumerable number of times, and yet every example of a species, every insect, every flower, every leaf, still appears just as carefully perfected as was the first of its kind; thus that nature by no means wearies and begins to bungle, but, with equally patient master-hand, perfects the last like the first: then we become conscious, first of all, that all human art is completely different, not merely in degree, but in kind, from the works of nature; and, next, that the working force, the natura naturans, in each of its innumerable works, in the least as in the greatest, in the last as in the first, is immediately present whole and undivided, from which it follows that, as such and in itself, it knows nothing of space and time. If we further reflect that the production of these hyperboles of all works of art costs nature absolutely nothing, so that, with inconceivable prodigality, she creates millions of organisms which never attain to maturity, and without sparing exposes every living thing to a thousand accidents, yet, on the other hand, if favoured by chance or directed by human purpose, readily affords millions of examples of a species of which hitherto there was only one, so that millions cost her no more than one; this also leads us to see that the multiplicity of things has its root in the nature of the knowledge of the subject, but is foreign to the thing in itself, *i.e.*, to the inner primary force which shows itself in things; that consequently space and time, upon which the possibility of all multiplicity depends, are mere forms of our perception; nay, that even that whole inconceivable ingenuity of structure associated with the reckless prodigality of the works upon which it has been expended ultimately springs simply from the way in which things are apprehended by us; for when the simple and indivisible original effort of the will exhibits itself as object in our cerebral knowledge, it must appear as an ingenious combination of separate parts, as means and ends of each other, accomplished with wonderful completeness.

The unity of that will, here referred to, which lies beyond the phenomenon, and in which we have recognised the inner nature of the phenomenal world, is a metaphysical unity, and consequently transcends the knowledge of it, *i.e.*, does not depend upon the functions of our intellect,

and therefore can not really be comprehended by it. Hence it arises that it opens to the consideration an abyss so profound that it admits of no thoroughly clear and systematically connected insight, but grants us only isolated glances, which enable us to recognise this unity in this and that relation of things, now in the subjective, now in the objective sphere, whereby, however, new problems are again raised, all of which I will not engage to solve, but rather appeal here to the words est quadam prodire tenus, more concerned to set up nothing false or arbitrarily invented than to give a thorough account of all; — at the risk of giving here only a fragmentary exposition.

If we call up to our minds and distinctly go through in thought the exceedingly acute theory of the origin of the planetary system, first put forth by Kant and later by Laplace, a theory of which it is scarcely possible to doubt the correctness, we see the lowest, crudest, and blindest forces of nature bound to the most rigid conformity to law, by means of their conflict for one and the same given matter, and the accidental results brought about by this produce the framework of the world, thus of the designedly prepared future dwelling-place of innumerable living beings, as a system of order and harmony, at which we are the more astonished the more distinctly and accurately we come to understand it. For example, if we see that every planet, with its present velocity, can only maintain itself exactly where it actually has its place, because if it were brought nearer to the sun it would necessarily fall into it, or if placed further from it would necessarily fly away from it; how, conversely, if we take the place as given, it can only remain there with its present velocity and no other, because if it went faster it would necessarily fly away from the sun, and if it went slower it would necessarily fall into it; that thus only one definite place is suitable to each definite velocity of a planet; and if we now see this solved by the fact that the same physical, necessary, and blindly acting cause which appointed it its place, at the same time and just by doing so, imparted to it exactly the only velocity suitable for this place, in consequence of the law of nature that a revolving body increases its velocity in proportion as its revolution becomes smaller; and, moreover, if finally we understand how endless permanence is assured to the whole system, by the fact that all the mutual disturbances of the course of the planets which unavoidably enter, must adjust themselves in time; how then it is just the irrationality of the periods of revolution of Jupiter and Saturn to each other that prevents their respective perturbations

from repeating themselves at one place, whereby they would become dangerous, and brings it about that, appearing seldom and always at a different place, they must sublate themselves again, like dissonances in music which are again resolved into harmony. By means of such considerations we recognise a design and perfection, such as could only have been brought about by the freest absolute will directed by the most penetrating understanding and the most acute calculation. And yet, under the guidance of that cosmogony of Laplace, so well thought out and so accurately calculated, we cannot prevent ourselves from seeing that perfectly blind forces of nature, acting according to unalterable natural laws, through their conflict and aimless play among themselves, could produce nothing else but this very framework of the world, which is equal to the work of an extraordinarily enhanced power of combination. Instead now, after the manner of Anaxagoras, of dragging in the aid of an intelligence known to us only from animal nature, and adapted only to its aims, an intelligence which, coming from without, cunningly made use of the existing forces of nature and their laws in order to carry out its ends, which are foreign to these, — we recognise in these lowest forces of nature themselves that same, one will, which indeed first manifests itself in them, and already in this manifestation striving after its goal, through its original laws themselves works towards its final end, to which therefore all that happens according to blind laws of nature must minister and correspond. And this indeed cannot be otherwise, because everything material is nothing but just the phenomenal appearance, the visibility, the objectivity of the will to live which is one. Thus even the lowest forces of nature themselves are animated by that same will, which afterwards, in the individual beings provided with intelligence, marvels at its own work, as the somnambulist wonders in the morning at what he has done in his sleep; or, more accurately, which is astonished at its own form which it beholds in the mirror. This unity which is here proved of the accidental with the intentional, of the necessary with the free, on account of which the blindest chances, which, however, rest upon universal laws of nature, are as it were the keys upon which the world-spirit plays its melodies so full of significance, — this unity, I say, is, as has already been remarked, an abyss in the investigation into which even philosophy can throw no full light, but only a glimmer.

But I now turn to a subjective consideration belonging to this place, to which, however, I am able to give still less distinctness than to the objective consideration which has just been set forth; for I shall only be able to express it by images and similes. Why is our consciousness brighter and more distinct the further it extends towards without, so that its greatest clearness lies in sense perception, which already half belongs to things outside us, — and, on the other hand, grows dimmer as we go in, and leads, if followed to its inmost recesses, to a darkness in which all knowledge ceases? Because, I say, consciousness presupposes individuality; but this belongs to the mere phenomenon, for it is conditioned by the forms of the phenomenon, space and time, as multiplicity of the similar. Our inner nature, on the other hand, has its root in that which is no longer phenomenon, but thing in itself, to which, therefore, the forms of the phenomenon do not extend; and thus the chief conditions of individuality are wanting, and with these the distinctness of consciousness falls off. In this root of existence the difference of beings ceases, like that of the radii of a sphere in the centre; and as in the sphere the surface is produced by the radii ending and breaking off, so consciousness is only possible where the true inner being runs out into the phenomenon, through whose forms the separate individuality becomes possible upon which consciousness depends, which is just on that account confined to phenomena. Therefore all that is distinct and thoroughly comprehensible in our consciousness always lies without upon this surface of the sphere. Whenever, on the contrary, we withdraw entirely from this, consciousness forsakes us, — in sleep, in death, to a certain extent also in magnetic or magic influences; for these all lead through the centre. But just because distinct consciousness, being confined to the surface of the sphere, is not directed towards the centre, it recognises other individuals certainly as of the same kind, but not as identical, which yet in themselves they are. Immortality of the individual might be compared to a point of the surface flying off at a tangent. But immortality, by virtue of the eternal nature of the inner being of the whole phenomenon, may be compared to the return of that point, on the radius, to the centre, of which the whole surface is just the extension. The will as the thing in itself is whole and undivided in every being, as the centre is an integral part of every radius; while the peripherical end of this radius is in the most rapid revolution, with the surface, which represents time and its content, the other end, at the centre, which represents eternity, remains in

the profoundest peace, because the centre is the point of which the rising half is not different from the sinking. Therefore in the Bhagavad-gita it is said: “Haud distributum animantibus, et quasi distributum tamen insidens, animantiumque sustentaculum id cognoscendum, edax et rursus genitale” (Lect. 13, 16 vers. Schlegel). Certainly we fall here into mystical and figurative language, but it is the only language in which anything can be said on this entirely transcendent theme. So this simile also may pass. The human race may be imagined as an animal compositum, a form of life of which many polypi, especially those which swim, such as Veretillum, Funiculina, and others, afford examples. As in these the head isolates each individual animal, and the lower part, with the common stomach, combines them all in the unity of one life process, so the brain with its consciousness isolates the human individual, while the unconscious part, the vegetative life with its ganglion system, into which in sleep the brain-consciousness disappears, like a lotus which nightly sinks in the flood, is a common life of all, by means of which in exceptional cases they can even communicate, as, for example, occurs when dreams communicate themselves directly, the thoughts of the mesmeriser pass into the somnambulist, and finally also in the magnetic or generally magical influence proceeding from intentional willing. Such an influence, if it occurs, is toto genere different from every other on account of the influxus physicus which takes place, for it is really an actio in distans which the will, certainly proceeding from the individual, yet performs in its metaphysical quality as the omnipresent substratum of the whole of nature. One might also say that as in the generatio æquivoca there sometimes and as an exception appears a weak residue of the original creative power of the will, which in the existing forms of nature has already done its work and is extinguished, so there may be, exceptionally, acting in these magical influences, as it were, a surplus of its original omnipotence, which completes its work and spends itself in the construction and maintenance of the organisms. I have spoken fully of this magical property of the will in “The Will in Nature,” and I gladly omit here discussions which have to appeal to uncertain facts, which yet cannot be altogether ignored or denied.

Chapter XXVI.[4] On Teleology.

The universal teleology or design of organised nature relative to the continuance of every existing being, together with the adaptation of organised to unorganised nature, cannot without violence enter into the connection of any philosophical system except that one which makes a will the basis of the existence of every natural being; a will which accordingly expresses its nature and tendency not merely in the actions, but already in the form of the phenomenal organism. In the preceding chapter I have merely indicated the account which our system of thought gives of this subject, since I have already expounded it in the passage of the first volume referred to below, and with special clearness and fulness in "The Will in Nature," under the rubric "Comparative Anatomy."

The astounding amazement which is wont to take possession of us when we consider the endless design displayed in the construction of organised beings ultimately rests upon the certainly natural but yet false assumption that that adaptation of the parts to each other, to the whole of the organism and to its aims in the external world, as we comprehend it and judge of it by means of knowledge, thus upon the path of the idea, has also come into being upon the same path; thus that as it exists for the intellect, it was also brought about by the intellect. We certainly can only bring about something regular and conforming to law, such, for example, as every crystal is, under the guidance of the law and the rule; and in the same way, we can only bring about something designed under the guidance of the conception of the end; but we are by no means justified in imputing this limitation of ours to nature, which is itself prior to all intellect, and whose action is entirely different in kind from ours, as was said in the preceding chapter. It accomplishes that which appears so designed and planned without reflection and without conception of an end, because without idea, which is of quite secondary origin. Let us first consider what is merely according to rule, not yet adapted to ends. The six equal radii of a snowflake, separating at equal angles, are measured beforehand by no knowledge; but it is the simple tendency of the original will, which so exhibits itself to knowledge when knowledge appears. As now here the will brings about the regular figure without mathematics, so also without physiology does it bring about the form which is organised and furnished with organs evidently adapted to

special ends. The regular form in space only exists for the perception, the perceptive form of which is space; so the design of the organism only exists for the knowing reason, the reflection of which is bound to the conceptions of end and means. If direct insight into the working of nature was possible for us, we would necessarily recognise that the wonder excited by teleology referred to above is analogous to that which that savage referred to by Kant in his explanation of the ludicrous felt when he saw the froth irresistibly foaming out of a bottle of beer which had just been opened, and expressed his wonder not that it should come out, but that any one had ever been able to get it in; for we also assume that the teleology of natural productions has been put in the same as it comes out for us. Therefore our astonishment at design may likewise be compared to that which the first productions of the art of printing excited in those who considered them under the supposition that they were works of the pen, and therefore had to resort to the assumption of the assistance of a devil in order to explain them. For, let it be said again, it is our intellect which by means of its own forms, space, time, and causality, apprehends as object the act of will, in itself metaphysical and indivisible, which exhibits itself in the phenomenon of an animal, — it is our intellect which first produces the multiplicity and diversity of the parts, and is then struck with amazement at their perfect agreement and conspiring together, which proceeds from the original unity; whereby then, in a certain sense, it marvels at its own work.

If we give ourselves up to the contemplation of the indescribably and infinitely ingenious construction of any animal, even if it were only the commonest insect, lose ourselves in admiration of it, and it now occurs to us that nature recklessly exposes even this exceedingly ingenious and highly complicated organism daily and by thousands to destruction by accident, animal rapacity, and human wantonness, this wild prodigality fills us with amazement; but our amazement is based upon an ambiguity of the conceptions, for we have in our minds the human work of art which is accomplished by the help of the intellect and by overcoming a foreign and resisting material, and therefore certainly costs much trouble. Nature’s works, on the contrary, however ingenious they may be, cost her absolutely no trouble; for here the will to work is already the work itself, since, as has already been said, the organism is merely the visibility of the will which is here present, brought about in the brain.

In consequence of the nature of organised beings which has been set forth, teleology, as the assumption of the adaptation of every part to its end, is a perfectly safe guide in considering the whole of organised nature; on the other hand, in a metaphysical regard, for the explanation of nature beyond the possibility of experience, it must only be regarded as valid in a secondary and subsidiary manner for the confirmation of principles of explanation which are otherwise established: for here it belongs to the problems which have to be given account of. Accordingly, if in some animal a part is found of which we do not see any use, we must never venture the conjecture that nature has produced it aimlessly, perhaps trifling, or out of mere caprice. Certainly it is possible to conceive something of this kind under the Anaxagorean assumption that the disposition of nature has been brought about by means of an ordering understanding, which, as such, obeys a foreign will; but not under the assumption that the true inner being (*i.e.*, outside of our idea) of every organism is simply and solely its own will; for then the existence of every part is conditioned by the circumstance that in some way it serves the will which here lies at its foundation, expresses and realises some tendency of it, and consequently in some way contributes to the maintenance of this organism. For apart from the will which manifests itself in it, and the conditions of the external world under which this has voluntarily undertaken to live, for the conflict with which its whole form and disposition is already adapted, nothing can have influenced it and determined its form and parts, thus no arbitrary power, no caprice. On this account everything in it must be designed; and therefore final causes (causæ finales) are the clue to the understanding of organised nature, as efficient causes (causæ efficientes) are the clue to the understanding of unorganised nature. It depends upon this, that if in anatomy or zoology, we cannot find the end or aim of an existing part, our understanding receives a shock similar to that which it receives in physics from an effect whose cause remains concealed; and as we assume the latter as necessary, so also we assume the former, and therefore go on searching for it, however long we may already have done so in vain. This is, for example, the case with the spleen, as to the use of which men never cease inventing hypotheses, till some day one shall have proved itself correct. So is it also with the large spiral-formed teeth of the babyroussa, the horn-shaped excrescences of certain caterpillars, and more of the like. Negative cases are also judged by

us according to the same rule; for example, that in a class which, as a whole, is so uniform as that of lizards, so important a part as the bladder is present in many species, while it is wanting in others; similarly that dolphins and certain cetacea related to them are entirely without olfactory nerves, while the rest of the cetacea and even fishes have them: there must be a reason which determines this.

Individual real exceptions to this universal law of design in organised nature have indeed been discovered, and with great surprise; but in these cases that exceptio firmat regulam applies, since they can be accounted for upon other grounds. Such, for example, is the fact that the tadpoles of the pipa toad have tails and gills, although, unlike all other tadpoles, they do not swim, but await their metamorphosis on the back of the mother; that the male kangaroo has the marsupial bones which in the female carry the pouch; that male mammals have breasts; that the Mus typhlus, a rat, has eyes, although very small ones, without any opening for them in the outer skin, which thus covers them, clothed with hair; and that the moles of the Apennines, and also two fishes — Murena cœcilia and Gastrobrauchus cœcus — are in the same case; of like kind is the Proteus anguinus. These rare and surprising exceptions to the rule of nature, which is otherwise so rigid, these contradictions with itself into which it falls, we must explain from the inner connection which the different kinds of phenomena have with each other, by virtue of the unity of that which manifests itself in them, and in consequence of which nature must hint at some thing in one, simply because another of the same type actually has it. Accordingly the male animal has a rudimentary form of an organ which is actually present in the female. As now here the difference of the sex cannot abolish the type of the species, so also the type of a whole order — for example, of the batrachia — asserts itself even where in one particular species (pipa) one of its determinations is superfluous. Still less can nature allow a determination (eyes) which belongs to the type of a whole division (Vertebrata) to vanish entirely without a trace, even if it is wanting in some particular species (Mus typhlus) as superfluous; but here also it must at least indicate in a rudimentary manner what it carries out in all the others.

Even from this point of view it is to some extent possible to see upon what depends that homology in the skeleton primarily of mammals, and in a wider sense of all vertebrates, which has been so fully explained, especially by Richard Owen in his "*Ostéologie comparée*," and on account of which,

for example, all mammals have seven cervical vertebræ, every bone of the human hand and arm finds its analogue in the fin of the whale, the skull of the bird in the egg has exactly as many bones as that of the human fœtus, &c. All this points to a principle which is independent of teleology, but which is yet the foundation upon which teleology builds, or the already given material for its works, and just that which Geoffroy St. Hilaire has explained as the "anatomical element." It is the unité de plan, the fundamental type of the higher animal world, as it were the arbitrarily chosen key upon which nature here plays.

Aristotle has already correctly defined the difference between the efficient cause (causa efficiens) and the final cause (causa finalis) in these words: "Δυο τροποι της αιτιας, το οὑ ἑνεκα και το εξ αναγκης, και δει λεγοντας τυγχανειν μαλιστα μεν αμφοιν." (Duo sunt causæ modi: alter cujus gratia, et alter e necessitate; ac potissimum utrumque eruere oportet.) *De part. anim.*, i. 1. The efficient cause is that whereby something is, the final cause that on account of which it is; the phenomenon to be explained has, in time, the former behind it, and the latter before it. Only in the case of the voluntary actions of animal beings do the two directly unite, for here the final cause, the end, appears as the motive; a motive, however, is always the true and proper cause of the action, is wholly and solely its efficient cause, the change preceding it which calls it forth, by virtue of which it necessarily appears, and without which it could not happen; as I have shown in my prize essay upon freedom. For whatever of a physiological nature one might wish to insert between the act of will and the corporeal movement, the will always remains here confessedly that which moves, and what moves it is the motive coming from without, thus the causa finalis; which consequently appears here as causa efficiens. Besides, we know from what has gone before that the bodily movement is one with the act of will, for it is merely its phenomenal appearance in cerebral perception. This union of the causa finalis with the efficient cause in the one phenomenon intimately known to us, which accordingly remains throughout our typical phenomenon, is certainly to be firmly retained; for it leads precisely to the conclusion that at least in organised nature, the knowledge of which has throughout final causes for its clue, a will is the forming power. In fact, we cannot otherwise distinctly think a final cause except as an end in view, *i.e.*, a motive. Indeed, if we carefully consider the final causes in nature in order to express their transcendent nature, we must not shrink from a

contradiction, and boldly say: the final cause is a motive which acts upon a being, by which it is not known. For certainly the termite nests are the motive which has produced the toothless muzzle of the ant-bear, and also its long extensile, glutinous tongue: the hard egg-shell which holds the chicken imprisoned is certainly the motive for the horny point with which its beak is provided in order to break through that shell, after which it throws it off as of no further use. And in the same way the laws of the reflection and refraction of light are the motive for the wonderfully ingenious and complex optical instrument, the human eye, which has the transparency of its cornea, the different density of its three humours, the form of its lens, the blackness of its choroid, the sensitiveness of its retina, the contracting power of its pupil, and its muscular system, accurately calculated according to those laws. But those motives acted before they were apprehended; it is not otherwise, however contradictory it may sound. For here is the transition of the physical into the metaphysical. But the latter we have already recognised in the will; therefore we must see that the will which extends an elephant's trunk towards an object is the same will which has also called it forth and formed it, anticipating objects.

It is in conformity with this that in the investigation of organised nature we are entirely referred to final causes, everywhere seek for these and explain everything from them. The efficient causes, on the contrary, here assume only a quite subordinate position as the mere tools of the final causes, and, just as in the case of the voluntary movement of the limbs, which is confessedly effected by external motives, they are rather assumed than pointed out. In explaining the physiological functions we certainly look about for the efficient causes, though for the most part in vain; but in explaining the origin of the parts we again look for them no more, but are satisfied with the final causes alone. At the most we have here some such general principle as that the larger the part is to be the stronger must be the artery that conducts blood to it; but of the actually efficient causes which bring about, for example, the eye, the ear, the brain, we know absolutely nothing. Indeed, even in explaining the mere functions the final cause is far more important and more to the point than the efficient; therefore, if the former alone is known we are instructed and satisfied with regard to the principal matter, while, on the other hand, the efficient cause alone helps us little. For example, if we really knew the efficient cause of the circulation of the blood, as we do not, but still seek it, this would help us little unless we

knew the final cause, that the blood must go into the lungs for the purpose of oxidation, and again flow back for the purpose of nourishing; but by the knowledge of this, even without the knowledge of the efficient cause, we have gained much light. Moreover, I am of opinion, as was said above, that the circulation of the blood has no properly efficient cause, but that the will is here as immediately active as in muscular movement where motives determine it by means of nerve conduction, so that here also the movement is called forth directly by the final cause; thus by the need of oxidation in the lungs, which here to a certain extent acts as a motive upon the blood, yet so that the mediation of knowledge is in this case wanting, because everything takes place in the interior of the organism. The so-called metamorphosis of plants, a thought lightly thrown out by Kaspar Wolf, which, under this hyperbolic title, Goethe pompously and with solemn delivery expounds as his own production, belongs to the class of explanations of organic nature from the efficient cause; although ultimately he only says that nature does not in the case of every production begin from the beginning and create out of nothing, but as it were, writing on in the same style, adds on to what already exists, makes use of the earlier forms, developed, and raised to higher power, to carry its work further: just as it has done in the ascending series of animals entirely in accordance with the law: Natura non facit saltus, et quod commodissimum in omnibus suis operationibus sequitur (*Arist. de incessu animalium, c. 2 et 8*). Indeed, to explain the blossom by pointing out in all its parts the form of the leaf seems to me almost the same as explaining the structure of a house by showing that all its parts, storeys, balconies, and garrets, are only composed of bricks and mere repetitions of the original unity of the brick. And not much better, though much more problematical, seems to me the explanation of the skull from vertebræ, although even here also it is a matter of course that the covering or case of the brain will not be absolutely different and entirely disparate from that of the spinal cord, of which it is the continuation and terminal knob, but will rather be a carrying out of the same kind of thing. This whole method of consideration belongs to the Homology of Richard Owen referred to above. On the other hand, it seems to me that the following explanation of the nature of the flower from its final cause, suggested by an Italian whose name has escaped me, is a far more satisfactory account to give. The end of the corolla is — (1.) Protection of the pistil and the stamina; (2.) by means of it the purified saps are prepared,

which are concentrated in the pollen and germs; (3.) from the glands of its base the essential oil distils which, for the most part as a fragrant vapour, surrounding the anthers and pistil, protects them to a certain extent from the influence of the damp air. It is also one of the advantages of final causes that every efficient cause always ultimately rests upon something that cannot be fathomed, a force of nature, *i.e.*, a qualitas occulta, and, therefore, it can only give a relative explanation; while the final cause within its sphere affords a sufficient and perfect explanation. It is true we are only perfectly content when we know both the efficient cause, also called by Aristotle ἡ αιτια εξ αναγκης, and the final cause, ἡ χαριν του βελτιονος, at once and yet separately, as their concurrence, their wonderful working together, then surprises us, and on account of it the best appears as the absolutely necessary, and the necessary again as if it were merely the best and not necessary; for then arises in us the dim perception that both causes, however different may be their origin, are yet connected in the root, in the nature of the thing in itself. But such a twofold knowledge is seldom attainable; in organised nature, because the efficient cause is seldom known to us; in unorganised nature, because the final cause remains problematical. However, I will illustrate this by a couple of examples as good as I find within the range of my physiological knowledge, for which physiologists may be able to substitute clearer and more striking ones. The louse of the negro is black. Final cause: its own safety. Efficient cause: because its nourishment is the black *rete Malpighi* of the negro. The multifarious, brilliant, and gay colouring of the plumage of tropical birds is explained, although only very generally, from the strong effect of the light in the tropics, as its efficient cause. As the final cause I would assign that those brilliant feathers are the gorgeous uniform in which the individuals of the innumerable species there, often belonging to the same genus, may recognise each other; so that each male may find his female. The same holds good of butterflies of different zones and latitudes. It has been observed that consumptive women, in the last stage of their illness, readily become pregnant, that the disease stops during pregnancy, but after delivery appears again worse than before, and now generally results in death: similarly that consumptive men generally beget another child in the last days of their life. The final cause here is that nature, always so anxiously concerned for the maintenance of the species, seeks to replace by a new individual the approaching loss of one in the prime of life; the efficient

cause, on the other hand, is the unusually excited state of the nervous system which occurs in the last period of consumption. From the same final cause is to be explained the analogous phenomenon that (according to Oken, *Die Zeugung*, p. 65) flies poisoned with arsenic still couple, and die in the act of copulation. The final cause of the pubes in both sexes, and of the Mons Veneris in the female, is that even in the case of very thin subjects the Ossa pubis shall not be felt, which might excite antipathy; the efficient cause, on the other hand, is to be sought in the fact that wherever the mucous membrane passes over to the outer skin, hair grows in the vicinity; and, secondly, also that the head and the genitals are to a certain extent opposite poles of each other, and therefore have various relations and analogies between them, among which is that of being covered with hair. The same efficient cause holds good also of the beard of the man; the final cause of it, I suppose, lies in the fact that the pathogonomic signs, thus the rapid alterations of the countenance betraying every movement of the mind, are principally visible in the mouth and its vicinity; therefore, in order to conceal these from the prying eye of the adversary, as something dangerous in bargaining, or in sudden emergencies, nature gave man the beard (which shows that homo homini lupus). The woman, on the other hand, could dispense with this; for with her dissimulation and command of countenance are inborn. As I have said, there must be far more apt examples to be found to show how the completely blind working of nature unites in the result with the apparently intentional, or, as Kant calls it, the mechanism of nature with its technic; which points to the fact that both have their common origin beyond their difference in the will as the thing in itself. Much would be achieved for the elucidation of this point of view, if, for example, we could find the efficient cause which carries the driftwood to the treeless polar lands, or that which has concentrated the dry land of our planet principally in the northern half of it; while it is to be regarded as the final cause of this that the winter of that half, because it occurs in the perihelion which accelerates the course of the earth, is eight days shorter, and hereby is also milder. Yet in considering unorganised nature the final cause is always ambiguous, and, especially when the efficient cause is found, leaves us in doubt whether it is not a merely subjective view, an aspect conditioned by our point of view. In this respect, however, it may be compared to many works of art; for example, to coarse mosaics, theatre decorations, and to the god Apennine at Pratolino, near Florence, composed of large masses of

rock, all of which only produce their effect at a distance, and vanish when we come near, because instead of them the efficient cause of their appearance now becomes visible: but the forms are yet actually existent, and are no mere imagination. Analogous to this, then, are the final causes in unorganised nature, if the efficient causes appear. Indeed, those who take a wide view of things would perhaps allow it to pass if I added that something similar is the case with omens.

For the rest, if any one desires to misuse the external design, which, as has been said, always remains ambiguous for physico-theological demonstrations, which is done even at the present day, though it is to be hoped only by Englishmen, there are in this class enough examples in contrarium, thus ateleological instances, to derange his conception. One of the strongest is presented by the unsuitableness of sea-water for drinking, in consequence of which man is never more exposed to the danger of dying of thirst than in the midst of the greatest mass of water on his planet. "Why, then, does the sea need to be salt?" let us ask our Englishman.

That in unorganised nature the final causes entirely withdraw into the background, so that an explanation from them alone is here no longer valid, but the efficient causes are rather indispensably required, depends upon the fact that the will which objectifies itself here also no longer appears in individuals which constitute a whole for themselves, but in forces of nature and their action, whereby end and means are too far separated for their relation to be clear and for us to recognise a manifestation of will in it. This already occurs in organised nature, in a certain degree, when the design is an external one, *i.e.*, the end lies in one individual and the means in another. Yet even here it remains unquestionable so long as the two belong to the same species, indeed it then becomes the more striking. Here we have first to count the reciprocally adapted organisation of the genitals of the two sexes, and then also many circumstances that assist the propagation of the species, for example, in the case of the Lampyris noctiluca (the glowworm) the circumstance that only the male, which does not shine, has wings to enable it to seek out the female; the wingless female, on the other hand, since it only comes out in the evening, possesses the phosphorescent light, so that the male may be able to find it. Yet in the case of the Lampyris Italica both sexes shine, which is an instance of the natural luxury of the South. But a striking, because quite special, example of the kind of design we are speaking of is afforded by the discovery made by Geoffroy St.

Hilaire, in his last years, of the more exact nature of the sucking apparatus of the cetacea. Since all sucking requires the action of respiration, it can only take place in the respirable medium itself, and not under water, where, however, the sucking young of the whale hangs on to the teats of the mother; now to meet this the whole mammary apparatus of the cetacea is so modified that it has become an injecting organ, and placed in the mouth of the young injects the milk into it without it requiring to suck. When, on the contrary, the individual that affords essential help to another belongs to an entirely different species, and even to another kingdom of nature, we will doubt this external design just as in unorganised nature; unless it is evident that the maintenance of the species depends upon it. But this is the case with many plants whose fructification only takes place by means of insects, which either bear the pollen to the stigma or bend the stamina to the pistil. The common barberry, many kinds of iris, and Aristolochia Clematitis cannot fructify themselves at all without the help of insects (*Chr. Cour.* Sprengel, *Entdecktes Geheimniss, &c.*, 1793; Wildenow, *Grundriss der Kräuterkunde*, 353). Very many diœcia, monœcia, and polygamia are in the same position. The reciprocal support which the plant and the insect worlds receive from each other will be found admirably described in Burdach's large Physiology, vol. i. § 263. He very beautifully adds: "This is no mechanical assistance, no make-shift, as if nature had made the plants yesterday, and had committed an error which she tries to correct to-day through the insect; it is rather a deep-lying sympathy between the plant and the animal worlds. It ought to reveal the identity of the two. Both, children of one mother, ought to subsist with each other and through each other." And further on: "But the organised world stands in such a sympathy with the unorganised world also," &c. A proof of this consensus naturæ is also afforded by the observation communicated in the second volume of the "Introduction into Entomology" by Kirby and Spence, that the insect eggs that pass the winter attached to the twigs of the trees, which serve as nourishment for their larvæ, are hatched exactly at the time at which the twig buds; thus, for example, the aphis of the birch a month earlier than that of the ash. Similarly, that the insects of perennial plants pass the winter upon these as eggs; but those of mere annuals, since they cannot do this, in the state of pupæ.

Three great men have entirely rejected teleology, or the explanation from final causes, and many small men have echoed them. These three are,

Lucretius, Bacon of Verulam, and Spinoza. But in the case of all three we know clearly enough the source of this aversion, namely, that they regarded it as inseparable from speculative theology, of which, however, they entertained so great a distrust (which Bacon indeed prudently sought to conceal) that they wanted to give it a wide berth. We find Leibnitz also entirely involved in this prejudice, for, with characteristic naïveté, he expresses it as something self-evident in his *Lettre à M. Nicaise* (*Spinozæ op. ed Paulus*, vol. ii. p. 672): "Les causes finales, ou ce qui est la même chose, la consideration de la sagesse divine dans l'ordre des choses." (The devil also même chose!) At the same point of view we find, indeed, Englishmen even at the present day. The Bridgewater-Treatise-men — Lord Brougham, &c. — nay, even Richard Owen also, in his "*Ostéologie Comparée*," thinks precisely as Leibnitz, which I have already found fault with in the first volume. To all these teleology is at once also theology, and at every instance of design recognised in nature, instead of thinking and learning to understand nature, they break at once into the childish cry, "Design! design!" then strike up the refrain of their old wives' philosophy, and stop their ears against all rational arguments, such as, however, the great Hume has already advanced against them.[5]

The ignorance of the Kantian philosophy now, after seventy years, which is really a disgrace to Englishmen of learning, is principally responsible for this whole outcast position of the English; and this ignorance, again, depends, at least in great measure, upon the nefarious influence of the detestable English clergy, with whom stultification of every kind is a thing after their own hearts, so that only they may be able still to hold the English nation, otherwise so intelligent, involved in the most degrading bigotry; therefore, inspired by the basest obscurantism, they oppose with all their might the education of the people, the investigation of nature, nay, the advancement of all human knowledge in general; and both by means of their connections and by means of their scandalous, unwarrantable wealth, which increases the misery of the people, they extend their influence even to university teachers and authors, who accordingly (for example, Th. Brown, "On Cause and Effect") resort to suppressions and perversions of every kind simply in order to avoid opposing even in a distant manner that "cold superstition" (as Pückler very happily designates their religion, or the current arguments in its favour).

But, on the other hand, the three great men of whom we are speaking, since they lived long before the dawn of the Kantian philosophy, are to be pardoned for their distrust of teleology on account of its origin; yet even Voltaire regarded the physico-theological proof as irrefutable. In order, however, to go into this somewhat more fully: first of all, the polemic of Lucretius (iv. 824-858) against teleology is so crude and clumsy that it refutes itself and convinces us of the opposite. But as regards Bacon (*De augm. scient.*, iii. 4), he makes, in the first place, no distinction with reference to the use of final causes between organised and unorganised nature (which is yet just the principal matter), for, in his examples of final causes, he mixes the two up together. Then he banishes final causes from physics to metaphysics; but the latter is for him, as it is still for many at the present day, identical with speculative theology. From this, then, he regards final causes as inseparable, and goes so far in this respect that he blames Aristotle because he has made great use of final causes, yet without connecting them with speculative theology (which I shall have occasion immediately especially to praise). Finally, Spinoza (*Eth.* i. *prop.* 36, *appendix*) makes it abundantly clear that he identifies teleology so entirely with physico-theology, against which he expresses himself with bitterness, that he explains Natura nihil frustra agere: hoc est, quod in usum hominum non sit: similarly, Omnia naturalia tanquam ad suum utile media considerant, et credunt aliquem alium esse, qui illa media paraverit; and also: Hinc statuerunt, Deos omnia in usum hominum fecisse et dirigere. Upon this, then, he bases his assertion: Naturam finem nullum sibi præfixum habere et omnes causas finales nihil, nisi humana esse figmenta. His aim merely was to block the path of theism; and he had quite rightly recognised the physico-theological proof as its strongest weapon. But it was reserved for Kant really to refute this proof, and for me to give the correct exposition of its material, whereby I have satisfied the maxim: Est enim verum index sui et falsi. But Spinoza did not know how else to help himself but by the desperate stroke of denying teleology itself, thus design in the works of nature — an assertion the monstrosity of which is at once evident to every one who has gained any accurate knowledge of organised nature. This limited point of view of Spinoza, together with his complete ignorance of nature, sufficiently prove his entire incompetence in this matter, and the folly of those who, upon his authority, believe they must judge contemptuously of final causes.

Aristotle, who just here shows his brilliant side, contrasts very advantageously with these modern philosophers. He goes unprejudiced to nature, knows of no physico-theology — such a thing has never entered his mind, — and he has never looked at the world for the purpose of seeing whether it was a bungled piece of work. He is in his heart pure from all this, for he also sets up hypotheses as to the origin of animals and men (*De generat. anim.*, iii. 11) without lighting upon the physico-theological train of thought. He always says: "ἡ φυσις ποιει (natura facit), never ἡ φυσις πεποιηται" (natura facta est). But after he has truly and diligently studied nature, he finds that it everywhere proceeds teleologically, and he says: "ματην ὁρωμεν ουδεν ποιουσαν την φυσιν" (naturam nihil frustra facere cernimus), *De respir.*, c. 10; and in the books, *De partibus animalium*, which are a comparative anatomy: "Ουδε περιεργον ουδεν, ουτε ματην ἡ φυσις ποιει. — Ἡ φυσις ἑνεκα του ποιει παντα. — Πανταχου δε λεγομεν τοδε τουδε ἑνεκα, ὁπου αν φαινηται τελος τι, προς ὁ ἡ κινησις περαινει; ὡστε ειναι φανερον, ὁτι εστι τι τοιουτον, ὁ δη και καλουμεν φυσιν. Επει το σωμα οργανον; ἑνεκα τινος γαρ ἑκαστον των μοριων, ομοιως τε και το ὁλον." (Nihil supervacaneum, nihil frustra natura facit. — Natura rei alicujus gratia facit omnia. — Rem autem hanc esse illius gratia asserere ubique solemus, quoties finem intelligimus aliquem, in quem motus terminetur; quocirca ejusmodi aliquid esse constat, quod Naturam vocamus. Est enim corpus instrumentum: nam membrum unumquodque rei alicujus gratia est, tum vero totum ipsum.) At greater length, p. 633 and 645 of the Berlin quarto edition, and also *De incessu animalium*, c. 2: "Ἡ φυσις ουδεν ποιει ματην, αλλ᾽ αει, εκ των ενδεχομενων τῃ ουσιᾳ, περι ἑκαστον γενος ζωου το αριστον." (Natura nihil frustra facit, sed semper ex iis, quæ cuique animalium generis essentiæ contingunt, id quod optimum est.) But he expressly recommends teleology at the end of the books *De generatione animalium*, and blames Democritus for having denied it, which is just what Bacon, in his prejudice, praises in him. Especially, however, in the "Physica," ii. 8, p. 198, Aristotle speaks ex professo of final causes, and establishes them as the true principle of the investigation of nature. In fact, every good and regular mind must, in considering organised nature, hit upon teleology, but unless it is determined by the preconceived opinions, by no means either upon physico-theology or upon the anthropo-teleology condemned by Spinoza. With regard to Aristotle generally, I wish further to

draw attention to the fact here, that his teaching, so far as it concerns unorganised nature, is very defective and unserviceable, as in the fundamental conceptions of mechanics and physics he accepts the most gross errors, which is the less pardonable, since before him the Pythagoreans and Empedocles had been upon the right path and had taught much better. Empedocles indeed, as we learn from Aristotle's second book, *De cælo* (c. 1, p. 284), had already grasped the conception of a tangential force arising from rotation, and counteracting gravity, which Aristotle again rejects. Quite the reverse, however, is Aristotle's relation to the investigation of organised nature. This is his field; here the wealth of his knowledge, the keenness of his observation, nay, sometimes the depth of his insight, astonish us. Thus, to give just one example, he already knew the antagonism in which in the ruminants the horns and the teeth of the upper jaw stand to each other, on account of which, therefore, the latter are wanting where the former are found, and conversely (*De partib. anim.*, iii. 2). Hence then, also his correct estimation of final causes.

Chapter XXVII. On Instinct And Mechanical Tendency.

It is as if nature had wished, in the mechanical tendencies of animals, to give the investigator an illustrative commentary upon her works, according to final causes and the admirable design of her organised productions which is thereby introduced. For these mechanical tendencies show most clearly that creatures can work with the greatest decision and definiteness towards an end which they do not know, nay, of which they have no idea. Such, for instance, is the bird's nest, the spider's web, the ant-lion's pitfall, the ingenious bee-hive, the marvellous termite dwelling, &c., at least for those individual animals that carry them out for the first time; for neither the form of the perfected work nor the use of it can be known to them. Precisely so, however, does organising nature work; and therefore in the preceding chapter I gave the paradoxical explanation of the final cause, that it is a motive which acts without being known. And as in working from mechanical tendency that which is active is evidently and confessedly the will, so is it also really the will which is active in the working of organising nature.

One might say, the will of animal creatures is set in motion in two different ways: either by motivation or by instinct; thus from without, or from within; by an external occasion, or by an internal tendency; the former is explicable because it lies before us without, the latter is inexplicable because it is merely internal. But, more closely considered, the contrast between the two is not so sharp, indeed ultimately it runs back into a difference of degree. The motive also only acts under the assumption of an inner tendency, *i.e.*, a definite quality of will which is called its character. The motive in each case only gives to this a definite direction — individualises it for the concrete case. So also instinct, although a definite tendency of the will, does not act entirely, like a spring, from within; but it also waits for some external circumstance necessarily demanded for its action, which at least determines the time of its manifestation; such is, for the migrating bird, the season of the year; for the bird that builds its nest, the fact of pregnancy and the presence of the material for the nest; for the bee it is, for the beginning of the structure, the basket or the hollow tree, and for the following work many individually appearing circumstances; for the spider, it is a well-adapted corner; for the caterpillar, the suitable leaf;

for egg-laying insects, the for the most part very specially determined and often rare place, where the hatched larvæ will at once find their nourishment, and so on. It follows from this that in works of mechanical tendency it is primarily the instinct of these animals that is active, yet subordinated also to their intellect. The instinct gives the universal, the rule; the intellect the particular, the application, in that it directs the detail of the execution, in which therefore the work of these animals clearly adapts itself to the circumstances of the existing case. According to all this, the difference between instinct and mere character is to be fixed thus: Instinct is a character which is only set in motion by a quite specially determined motive, and on this account the action that proceeds from it is always exactly of the same kind; while the character which is possessed by every species of animal and every individual man is certainly a permanent and unalterable quality of will, which can yet be set in motion by very different motives, and adapts itself to these; and on account of this the action proceeding from it may, according to its material quality, be very different, but yet will always bear the stamp of the same character, and will therefore express and reveal this; so that for the knowledge of this character the material quality of the action in which it appears is essentially a matter of indifference. Accordingly we might explain instinct as a character which is beyond all measure one-sided and strictly determined. It follows from this exposition that being determined by mere motivation presupposes a certain width of the sphere of knowledge, and consequently a more fully developed intellect: therefore it is peculiar to the higher animals, quite pre-eminently, however, to man; while being determined by instinct only demands as much intellect as is necessary to apprehend the one quite specially determined motive, which alone and exclusively becomes the occasion for the manifestation of the instinct. Therefore it is found in the case of an exceedingly limited sphere of knowledge, and consequently, as a rule, and in the highest degree, only in animals of the lower classes, especially insects. Since, accordingly, the actions of these animals only require an exceedingly simple and small motivation from without, the medium of this, thus the intellect or the brain, is very slightly developed in them, and their outward actions are for the most part under the same guidance as the inner, follow upon mere stimuli, physiological functions, thus the ganglion system. This is, then, in their case excessively developed; their principal nerve-stem runs under the belly in the form of two cords, which at every

limb of the body form a ganglion little inferior to the brain in size, and, according to Cuvier, this nerve-stem is an analogue not so much of the spinal cord as of the great sympathetic nerve. According to all this, instinct and action through mere motivation, stand in a certain antagonism, in consequence of which the former has its maximum in insects, and the latter in man, and the actuation of other animals lies between the two in manifold gradations according as in each the cerebral or the ganglion system is preponderatingly developed. Just because the instinctive action and the ingenious contrivances of insects are principally directed from the ganglion system, if we regard them as proceeding from the brain alone, and wish to explain them accordingly, we fall into absurdities, because we then apply a false key. The same circumstance, however, imparts to their action a remarkable likeness to that of somnambulists, which indeed is also explained as arising from the fact that, instead of the brain, the sympathetic nerve has undertaken the conduct of the outward actions also; insects are accordingly, to a certain extent, natural somnambulists. Things which we cannot get at directly we must make comprehensible to ourselves by means of an analogy. What has just been referred to will accomplish this in a high degree when assisted by the fact that in Kieser's "*Tellurismus*" (vol. ii. p. 250) a case is mentioned "in which the command of the mesmerist to the somnambulist to perform a definite action in a waking state was carried out by him when he awoke, without remembering the command." Thus it was as if he must perform that action without rightly knowing why. Certainly this has the greatest resemblance to what goes on in the case of mechanical instincts in insects. The young spider feels that it must spin its web, although it neither knows nor understands the aim of it. We are also reminded here of the dæmon of Socrates, on account of which he had the feeling that he must leave undone some action expected of him, or lying near him, without knowing why — for his prophetic dream about it was forgotten. We have in our own day quite well-authenticated cases analogous to this; therefore I only briefly call these to mind. One had taken his passage on a ship, but when it was about to sail he positively would not go on board without being conscious of a reason; — the ship went down. Another goes with companions to a powder magazine; when he has arrived in its vicinity he absolutely will not go any further, but turns hastily back, seized with anxiety he knows not why; — the magazine blows up. A third upon the ocean feels moved one night, without any reason, not to undress, but lays

himself on the bed in his clothes and boots, and even with his spectacles on; — in the night the ship goes on fire, and he is among the few who save themselves in the boat. All this depends upon the dull after-effect of forgotten fatidical dreams, and gives us the key to an analogous understanding of instinct and mechanical tendencies.

On the other hand, as has been said, the mechanical tendencies of insects reflect much light upon the working of the unconscious will in the inner functions of the organism and in its construction. For without any difficulty we can see in the ant-hill or the beehive the picture of an organism explained and brought to the light of knowledge. In this sense Burdach says (*Physiologie*, vol. ii. p. 22): "The formation and depositing of the eggs is the part of the queen-bee, and the care for the cultivation of them falls to the workers; thus in the former the ovary, and in the latter the uterus, is individualised." In the insect society, as in the animal organism, the vita propria of each part is subordinated to the life of the whole, and the care for the whole precedes that for particular existence; indeed the latter is only conditionally willed, the former unconditionally; therefore the individuals are even sacrificed occasionally for the whole, as we allow a limb to be taken off in order to save the whole body. Thus, for example, if the path is closed by water against the march of the ants, those in front boldly throw themselves in until their corpses are heaped up into a dam for those that follow. When the drones have become useless they are stung to death. Two queens in the hive are surrounded, and must fight with each other till one of them loses its life. The ant-mother bites its own wings off after it has been impregnated, for they would only be a hindrance to it in the work that is before it of tending the new family it is about to found under the earth (Kirby and Spence, vol. i.) As the liver will do nothing more than secrete gall for the service of the digestion, nay, will only itself exist for this end — and so with every other part — the working bees also will do nothing more than collect honey, secrete wax, and make cells for the brood of the queen; the drones nothing more than impregnate; the queen nothing but deposit eggs; thus all the parts work only for the maintenance of the whole which alone is the unconditional end, just like the parts of the organism. The difference is merely that in the organism the will acts perfectly blindly in its primary condition; in the insect society, on the other hand, the thing goes on already in the light of knowledge, to which, however, a decided co-operation and individual choice is only left in the accidents of detail, where

it gives assistance and adopts what has to be carried out to the circumstances. But the insects will the end as a whole without knowing it; just like organised nature working according to final causes; even the choice of the means is not as a whole left to their knowledge, but only the more detailed disposition of them. Just on this account, however, their action is by no means automatic, which becomes most distinctly visible if one opposes obstacles to their action. For example, the caterpillar spins itself in leaves without knowing the end; but if we destroy the web it skilfully repairs it. Bees adapt their hive at the first to the existing circumstances, and subsequent misfortunes, such as intentional destruction, they meet in the way most suitable to the special case (Kirby and Spence, *Introduc. to Entomol.*; Huber, *Des abeilles*). Such things excite our astonishment, because the apprehension of the circumstances and the adaptation to these is clearly a matter of knowledge; while we believe them capable once for all of the most ingenious preparation for the coming race and the distant future, well knowing that in this they are not guided by knowledge, for a forethought of that kind proceeding from knowledge demands an activity of the brain rising to the level of reason. On the other hand, the intellect even of the lower animals is sufficient for the modifying and arranging of the particular case according to the existing or appearing circumstances; because, guided by instinct, it has only to fill up the gaps which this leaves. Thus we see ants carry off their larvæ whenever the place is too damp, and bring them back again when it becomes dry. They do not know the aim of this, thus are not guided in it by knowledge; but the choice of the time at which the place is no longer suitable for the larvæ, and also of the place to which they now bring them, is left to their knowledge. I wish here also to mention a fact which some one related to me verbally from his own experience, though I have since found that Burdach quotes it from Gleditsch. The latter, in order to test the burying-beetle (Necrophorus vespillo), had tied a dead frog lying upon the ground to a string, the upper end of which was fastened to a stick stuck obliquely in the ground. Now after several burying-beetles had, according to their custom, undermined the frog, it could not, as they expected, sink into the ground; after much perplexed running hither and thither they undermined the stick also. To this assistance rendered to instinct, and that repairing of the works of mechanical tendency, we find in the organism the healing power of nature analogous, which not only heals wounds, replacing even bone and nerve

substance, but, if through the injury of a vein or nerve branch a connection is interrupted, opens a new connection by means of enlargement of other veins or nerves, nay, perhaps even by producing new branches; which further makes some other part or function take the place of a diseased part or function; in the case of the loss of an eye sharpens the other, or in the case of the loss of one of the senses sharpens all the rest; which even sometimes closes an intestinal wound, in itself fatal, by the adhesion of the mesentery or the peritoneum; in short, seeks to meet every injury and every disturbance in the most ingenious manner. If, on the other hand, the injury is quite incurable, it hastens to expedite death, and indeed the more so the higher is the species of the organism, thus the greater its sensibility. Even this has its analogue in the instinct of insects. The wasps, for instance, who through the whole summer have with great care and labour fed their larvæ on the produce of their plundering, but now, in October, see the last generation of them facing starvation, sting them to death (Kirby and Spence, vol. i. p. 374). Nay, still more curious and special analogies may be found; for example, this: if the female humble-bee (Apis terrestris, bombylius) lays eggs, the working humble-bees are seized with a desire to devour them, which lasts from six to eight hours and is satisfied unless the mother keeps them off and carefully guards the eggs. But after this time the working humble-bees show absolutely no inclination to eat the eggs even when offered to them; on the contrary, they now become the zealous tenders and nourishers of the larvæ now being hatched out. This may without violence be taken as an analogue of children's complaints, especially teething, in which it is just the future nourishers of the organism making an attack upon it which so often costs it its life. The consideration of all these analogies between organised life and the instinct, together with the mechanical tendencies of the lower animals, serves ever more to confirm the conviction that the will is the basis of the one as of the other, for it shows here also the subordinate rôle of knowledge in the action of the will, sometimes more, sometimes less, confined, and sometimes wanting altogether.

But in yet another respect instincts and the animal organisation reciprocally illustrate each other: through the anticipation of the future which appears in both. By means of instincts and mechanical tendencies animals care for the satisfaction of wants which they do not yet feel, nay, not only for their own wants, but even for those of the future brood. Thus

they work for an end which is as yet unknown to them. This goes so far, as I have illustrated by the example of the Bombex in "The Will in Nature" (second edit. p. 45, third edit. p. 47), that they pursue and kill in advance the enemies of their future eggs. In the same way we see the future wants of an animal, its prospective ends, anticipated in its whole corporisation by the organised implements for their attainment and satisfaction; from which, then, proceeds that perfect adaptation of the structure of every animal to its manner of life, that equipment of it with the needful weapons to attack its prey and to ward off its enemies, and that calculation of its whole form with reference to the element and the surroundings in which it has to appear as a pursuer, which I have fully described in my work on the will in nature under the rubric "Comparative Anatomy." All these anticipations, both in the instinct and in the organisation of animals, we might bring under the conception of a knowledge a priori, if knowledge lay at their foundation at all. But this is, as we have shown, not the case. Their source lies deeper than the sphere of knowledge, in the will as the thing in itself, which as such remains free even from the forms of knowledge; therefore with reference to it time has no significance, consequently the future lies as near it as the present.

Chapter XXVIII.[6] Characterisation Of The Will To Live.

Our second book closed with the question as to the goal and aim of that will which had shown itself to be the inner nature of all things in the world. The following remarks may serve to supplement the answer to this question given there in general terms, for they lay down the character of the will as a whole.

Such a characterisation is possible because we have recognised as the inner nature of the world something thoroughly real and empirically given. On the other hand, the very name "world-soul," by which many have denoted that inner being, gives instead of this a mere ens rationis; for "soul" signifies an individual unity of consciousness which clearly does not belong to that nature, and in general, since the conception "soul" supposes knowing and willing in inseparable connection and yet independent of the animal organism, it is not to be justified, and therefore not to be used. The word should never be applied except in a metaphorical sense, for it is much more insidious than ψυχη or anima, which signify breath.

Much more unsuitable, however, is the way in which so-called pantheists express themselves, whose whole philosophy consists chiefly in this, that they call the inner nature of the world, which is unknown to them, "God;" by which indeed they imagine they have achieved much. According to this, then, the world would be a theophany. But let one only look at it: this world of constantly needy creatures, who continue for a time only by devouring one another, fulfil their existence in anxiety and want, and often suffer terrible miseries, till at last they fall into the arms of death; whoever distinctly looks upon this will allow that Aristotle was right in saying: "ἡ φυσις δαιομονια, αλλ᾽ ου θεια εστι" (Natura dæmonia est, non divina), *De divinat.*, c. 2, p. 463; nay, he will be obliged to confess that a God who could think of changing Himself into such a world as this must certainly have been tormented by the devil. I know well that the pretended philosophers of this century follow Spinoza in this, and think themselves thereby justified. But Spinoza had special reasons for thus naming his one substance, in order, namely, to preserve at least the word, although not the thing. The stake of Giordano Bruno and of Vanini was still fresh in the memory; they also had been sacrificed to that God for whose honour incomparably more human sacrifices have bled than on the altars of all

heathen gods of both hemispheres together. If, then, Spinoza calls the world God, it is exactly the same thing as when Rousseau in the "*Contrat social*," constantly and throughout denotes the people by the word le souverain; we might also compare it with this, that once a prince who intended to abolish the nobility in his land, in order to rob no one of his own, hit upon the idea of ennobling all his subjects. Those philosophers of our day have certainly one other ground for the nomenclature we are speaking of, but it is no more substantial. In their philosophising they all start, not from the world or our consciousness of it, but from God, as something given and known; He is not their quæsitum, but their datum. If they were boys I would then explain to them that this is a petitio principii, but they know this as well as I do. But since Kant has shown that the path of the earlier dogmatism, which proceeded honestly, the path from the world to a God, does not lead there, these gentlemen now imagine they have found a fine way of escape and made it cunningly. Will the reader of a later age pardon me for detaining him with persons of whom he has never heard.

Every glance at the world, to explain which is the task of the philosopher, confirms and proves that will to live, far from being an arbitrary hypostasis or an empty word, is the only true expression of its inmost nature. Everything presses and strives towards existence, if possible organised existence, *i.e.*, life, and after that to the highest possible grade of it. In animal nature it then becomes apparent that will to live is the keynote of its being, its one unchangeable and unconditioned quality. Let any one consider this universal desire for life, let him see the infinite willingness, facility, and exuberance with which the will to live presses impetuously into existence under a million forms everywhere and at every moment, by means of fructification and of germs, nay, when these are wanting, by means of generatio æquivoca, seizing every opportunity, eagerly grasping for itself every material capable of life: and then again let him cast a glance at its fearful alarm and wild rebellion when in any particular phenomenon it must pass out of existence; especially when this takes place with distinct consciousness. Then it is precisely the same as if in this single phenomenon the whole world would be annihilated for ever, and the whole being of this threatened living thing is at once transformed into the most desperate struggle against death and resistance to it. Look, for example, at the incredible anxiety of a man in danger of his life, the rapid and serious participation in this of every witness of it, and the boundless rejoicing at his

deliverance. Look at the rigid terror with which a sentence of death is heard, the profound awe with which we regard the preparations for carrying it out, and the heartrending compassion which seizes us at the execution itself. We would then suppose there was something quite different in question than a few less years of an empty, sad existence, embittered by troubles of every kind, and always uncertain: we would rather be amazed that it was a matter of any consequence whether one attained a few years earlier to the place where after an ephemeral existence he has billions of years to be. In such phenomena, then, it becomes visible that I am right in declaring that the will to live is that which cannot be further explained, but lies at the foundation of all explanations, and that this, far from being an empty word, like the absolute, the infinite, the idea, and similar expressions, is the most real thing we know, nay, the kernel of reality itself.

But if now, abstracting for a while from this interpretation drawn from our inner being, we place ourselves as strangers over against nature, in order to comprehend it objectively, we find that from the grade of organised life upwards it has only one intention — that of the maintenance of the species. To this end it works, through the immense superfluity of germs, through the urgent vehemence of the sexual instinct, through its willingness to adapt itself to all circumstances and opportunities, even to the production of bastards, and through the instinctive maternal affection, the strength of which is so great that in many kinds of animals it even outweighs self-love, so that the mother sacrifices her life in order to preserve that of the young. The individual, on the contrary, has for nature only an indirect value, only so far as it is the means of maintaining the species. Apart from this its existence is to nature a matter of indifference; indeed nature even leads it to destruction as soon as it has ceased to be useful for this end. Why the individual exists would thus be clear; but why does the species itself exist? That is a question which nature when considered merely objectively cannot answer. For in vain do we seek by contemplating her for an end of this restless striving, this ceaseless pressing into existence, this anxious care for the maintenance of the species. The strength and time of the individuals are consumed in the effort to procure sustenance for themselves and their young, and are only just sufficient, sometimes even not sufficient, for this. Even if here and there a surplus of strength, and therefore of comfort — in the case of the one rational species also of knowledge — remains, this is much too insignificant to pass for the end of that whole process of nature.

The whole thing, when regarded thus purely objectively, and indeed as extraneous to us, looks as if nature was only concerned that of all her (Platonic) Ideas, *i.e.*, permanent forms, none should be lost. Accordingly, as if she had so thoroughly satisfied herself with the fortunate discovery and combination of these Ideas (for which the three preceding occasions on which she stocked the earth's surface with animals were only the preparation), that now her only fear is lest any one of these beautiful fancies should be lost, *i.e.*, lest any one of these forms should disappear from time and the causal series. For the individuals are fleeting as the water in the brook; the Ideas, on the contrary, are permanent, like its eddies: but the exhaustion of the water would also do away with the eddies. We would have to stop at this unintelligible view if nature were known to us only from without, thus were given us merely objectively, and we accepted it as it is comprehended by knowledge, and also as sprung from knowledge, *i.e.*, in the sphere of the idea, and were therefore obliged to confine ourselves to this province in solving it. But the case is otherwise, and a glance at any rate is afforded us into the interior of nature; inasmuch as this is nothing else than our own inner being, which is precisely where nature, arrived at the highest grade to which its striving could work itself up, is now by the light of knowledge found directly in self-consciousness. Here the will shows itself to us as something toto genere different from the idea, in which nature appears unfolded in all her (Platonic) Ideas; and it now gives us, at one stroke, the explanation which could never be found upon the objective path of the idea. Thus the subjective here gives the key for the exposition of the objective. In order to recognise, as something original and unconditioned, that exceedingly strong tendency of all animals and men to retain life and carry it on as long as possible — a tendency which was set forth above as characteristic of the subjective, or of the will — it is necessary to make clear to ourselves that this is by no means the result of any objective knowledge of the worth of life, but is independent of all knowledge; or, in other words, that those beings exhibit themselves, not as drawn from in front, but as impelled from behind.

If with this intention we first of all review the interminable series of animals, consider the infinite variety of their forms, as they exhibit themselves always differently modified according to their element and manner of life, and also ponder the inimitable ingenuity of their structure and mechanism, which is carried out with equal perfection in every

individual; and finally, if we take into consideration the incredible expenditure of strength, dexterity, prudence, and activity which every animal has ceaselessly to make through its whole life; if, approaching the matter more closely, we contemplate the untiring diligence of wretched little ants, the marvellous and ingenious industry of the bees, or observe how a single burying-beetle (Necrophorus vespillo) buries a mole of forty times its own size in two days in order to deposit its eggs in it and insure nourishment for the future brood (*Gleditsch, Physik. Bot. Œkon. Abhandl.*, iii. 220), at the same time calling to mind how the life of most insects is nothing but ceaseless labour to prepare food and an abode for the future brood which will arise from their eggs, and which then, after they have consumed the food and passed through the chrysalis state, enter upon life merely to begin again from the beginning the same labour; then also how, like this, the life of the birds is for the most part taken up with their distant and laborious migrations, then with the building of their nests and the collecting of food for the brood, which itself has to play the same rôle the following year; and so all work constantly for the future, which afterwards makes bankrupt; — then we cannot avoid looking round for the reward of all this skill and trouble, for the end which these animals have before their eyes, which strive so ceaselessly — in short, we are driven to ask: What is the result? what is attained by the animal existence which demands such infinite preparation? And there is nothing to point to but the satisfaction of hunger and the sexual instinct, or in any case a little momentary comfort, as it falls to the lot of each animal individual, now and then in the intervals of its endless need and struggle. If we place the two together, the indescribable ingenuity of the preparations, the enormous abundance of the means, and the insufficiency of what is thereby aimed at and attained, the insight presses itself upon us that life is a business, the proceeds of which are very far from covering the cost of it. This becomes most evident in some animals of a specially simple manner of life. Take, for example, the mole, that unwearied worker. To dig with all its might with its enormous shovel claws is the occupation of its whole life; constant night surrounds it; its embryo eyes only make it avoid the light. It alone is truly an animal nocturnum; not cats, owls, and bats, who see by night. But what, now, does it attain by this life, full of trouble and devoid of pleasure? Food and the begetting of its kind; thus only the means of carrying on and beginning anew the same doleful course in new individuals. In such examples it becomes clear that

there is no proportion between the cares and troubles of life and the results or gain of it. The consciousness of the world of perception gives a certain appearance of objective worth of existence to the life of those animals which can see, although in their case this consciousness is entirely subjective and limited to the influence of motives upon them. But the blind mole, with its perfect organisation and ceaseless activity, limited to the alternation of insect larvæ and hunger, makes the disproportion of the means to the end apparent. In this respect the consideration of the animal world left to itself in lands uninhabited by men is also specially instructive. A beautiful picture of this, and of the suffering which nature prepares for herself without the interference of man, is given by Humboldt in his "*Ansichten der Natur*" (second edition, p. 30 *et seq.*); nor does he neglect to cast a glance (p. 44) at the analogous suffering of the human race, always and everywhere at variance with itself. Yet in the simple and easily surveyed life of the brutes the emptiness and vanity of the struggle of the whole phenomenon is more easily grasped. The variety of the organisations, the ingenuity of the means, whereby each is adapted to its element and its prey contrasts here distinctly with the want of any lasting final aim; instead of which there presents itself only momentary comfort, fleeting pleasure conditioned by wants, much and long suffering, constant strife, bellum omnium, each one both a hunter and hunted, pressure, want, need, and anxiety, shrieking and howling; and this goes on in secula seculorum, or till once again the crust of the planet breaks. Yunghahn relates that he saw in Java a plain far as the eye could reach entirely covered with skeletons, and took it for a battlefield; they were, however, merely the skeletons of large turtles, five feet long and three feet broad, and the same height, which come this way out of the sea in order to lay their eggs, and are then attacked by wild dogs (Canis rutilans), who with their united strength lay them on their backs, strip off their lower armour, that is, the small shell of the stomach, and so devour them alive. But often then a tiger pounces upon the dogs. Now all this misery repeats itself thousands and thousands of times, year out, year in. For this, then, these turtles are born. For whose guilt must they suffer this torment? Wherefore the whole scene of horror? To this the only answer is: it is thus that the will to live objectifies itself.[7] Let one consider it well and comprehend it in all its objectifications; and then one will arrive at an understanding of its nature and of the world; but not if one frames general conceptions and builds card houses out of them. The

comprehension of the great drama of the objectification of the will to live, and the characterisation of its nature, certainly demands somewhat more accurate consideration and greater thoroughness than the dismissal of the world by attributing to it the title of God, or, with a silliness which only the German fatherland offers and knows how to enjoy, explaining it as the "Idea in its other being," in which for twenty years the simpletons of my time have found their unutterable delight. Certainly, according to pantheism or Spinozism, of which the systems of our century are mere travesties, all that sort of thing reels itself off actually without end, straight on through all eternity. For then the world is a God, ens perfectissimum, *i.e.*, nothing better can be or be conceived. Thus there is no need of deliverance from it; and consequently there is none. But why the whole tragi-comedy exists cannot in the least be seen; for it has no spectators, and the actors themselves undergo infinite trouble, with little and merely negative pleasure.

Let us now add the consideration of the human race. The matter indeed becomes more complicated, and assumes a certain seriousness of aspect; but the fundamental character remains unaltered. Here also life presents itself by no means as a gift for enjoyment, but as a task, a drudgery to be performed; and in accordance with this we see, in great and small, universal need, ceaseless cares, constant pressure, endless strife, compulsory activity, with extreme exertion of all the powers of body and mind. Many millions, united into nations, strive for the common good, each individual on account of his own; but many thousands fall as a sacrifice for it. Now senseless delusions, now intriguing politics, incite them to wars with each other; then the sweat and the blood of the great multitude must flow, to carry out the ideas of individuals, or to expiate their faults. In peace industry and trade are active, inventions work miracles, seas are navigated, delicacies are collected from all ends of the world, the waves engulf thousands. All strive, some planning, others acting; the tumult is indescribable. But the ultimate aim of it all, what is it? To sustain ephemeral and tormented individuals through a short span of time in the most fortunate case with endurable want and comparative freedom from pain, which, however, is at once attended with ennui; then the reproduction of this race and its striving. In this evident disproportion between the trouble and the reward, the will to live appears to us from this point of view, if taken objectively, as a fool, or subjectively, as a delusion, seized by which everything living works with the utmost exertion of its strength for something that is of no value. But when we

consider it more closely, we shall find here also that it is rather a blind pressure, a tendency entirely without ground or motive.

The law of motivation, as was shown in § 29 of the first volume, only extends to the particular actions, not to willing as a whole and in general. It depends upon this, that if we conceive of the human race and its action as a whole and universally, it does not present itself to us, as when we contemplate the particular actions, as a play of puppets who are pulled after the ordinary manner by threads outside them; but from this point of view, as puppets which are set in motion by internal clockwork. For if, as we have done above, one compares the ceaseless, serious, and laborious striving of men with what they gain by it, nay, even with what they ever can gain, the disproportion we have pointed out becomes apparent, for one recognises that that which is to be gained, taken as the motive-power, is entirely insufficient for the explanation of that movement and that ceaseless striving. What, then, is a short postponement of death, a slight easing of misery or deferment of pain, a momentary stilling of desire, compared with such an abundant and certain victory over them all as death? What could such advantages accomplish taken as actual moving causes of a human race, innumerable because constantly renewed, which unceasingly moves, strives, struggles, grieves, writhes, and performs the whole tragi-comedy of the history of the world, nay, what says more than all, perseveres in such a mock-existence as long as each one possibly can? Clearly this is all inexplicable if we seek the moving causes outside the figures and conceive the human race as striving, in consequence of rational reflection, or something analogous to this (as moving threads), after those good things held out to it, the attainment of which would be a sufficient reward for its ceaseless cares and troubles. The matter being taken thus, every one would rather have long ago said, "Le jeu ne vaut pas la chandelle," and have gone out. But, on the contrary, every one guards and defends his life, like a precious pledge intrusted to him under heavy responsibility, under infinite cares and abundant misery, even under which life is tolerable. The wherefore and the why, the reward for this, certainly he does not see; but he has accepted the worth of that pledge without seeing it, upon trust and faith, and does not know what it consists in. Hence I have said that these puppets are not pulled from without, but each bears in itself the clockwork from which its movements result. This is the will to live, manifesting itself as an untiring machine, an irrational tendency, which has not its sufficient reason

in the external world. It holds the individuals firmly upon the scene, and is the primum mobile of their movements; while the external objects, the motives, only determine their direction in the particular case; otherwise the cause would not be at all suitable to the effect. For, as every manifestation of a force of nature has a cause, but the force of nature itself none, so every particular act of will has a motive, but the will in general has none: indeed at bottom these two are one and the same. The will, as that which is metaphysical, is everywhere the boundary-stone of every investigation, beyond which it cannot go. From the original and unconditioned nature of the will, which has been proved, it is explicable that man loves beyond everything else an existence full of misery, trouble, pain, and anxiety, and, again, full of ennui, which, if he considered and weighed it purely objectively, he would certainly abhor, and fears above all things the end of it, which is yet for him the one thing certain.[8] Accordingly we often see a miserable figure, deformed and shrunk with age, want, and disease, implore our help from the bottom of his heart for the prolongation of an existence, the end of which would necessarily appear altogether desirable if it were an objective judgment that determined here. Thus instead of this it is the blind will, appearing as the tendency to life, the love of life, and the sense of life; it is the same which makes the plants grow. This sense of life may be compared to a rope which is stretched above the puppet-show of the world of men, and on which the puppets hang by invisible threads, while apparently they are supported only by the ground beneath them (the objective value of life). But if the rope becomes weak the puppet sinks; if it breaks the puppet must fall, for the ground beneath it only seemed to support it: *i.e.*, the weakening of that love of life shows itself as hypochondria, spleen, melancholy: its entire exhaustion as the inclination to suicide, which now takes place on the slightest occasion, nay, for a merely imaginary reason, for now, as it were, the man seeks a quarrel with himself, in order to shoot himself dead, as many do with others for a like purpose; —indeed, upon necessity, suicide is resorted to without any special occasion. (Evidence of this will be found in Esquirol, *Des maladies mentales*, 1838.) And as with the persistence in life, so is it also with its action and movement. This is not something freely chosen; but while every one would really gladly rest, want and ennui are the whips that keep the top spinning. Therefore the whole and every individual bears the stamp of a forced condition; and every one, in that, inwardly weary, he longs for rest, but yet

must press forward, is like his planet, which does not fall into the sun only because a force driving it forward prevents it. Therefore everything is in continual strain and forced movement, and the course of the world goes on, to use an expression of Aristotle's (*De cælo*, ii. 13), "ου φυσει, αλλα βιᾳ" (Motu, non naturali sed violento). Men are only apparently drawn from in front; really they are pushed from behind; it is not life that tempts them on, but necessity that drives them forward. The law of motivation is, like all causality, merely the form of the phenomenon. We may remark in passing that this is the source of the comical, the burlesque, the grotesque, the ridiculous side of life; for, urged forward against his will, every one bears himself as best he can, and the straits that thus arise often look comical enough, serious as is the misery which underlies them.

In all these considerations, then, it becomes clear to us that the will to live is not a consequence of the knowledge of life, is in no way a conclusio ex præmissis, and in general is nothing secondary. Rather, it is that which is first and unconditioned, the premiss of all premisses, and just on that account that from which philosophy must start, for the will to live does not appear in consequence of the world, but the world in consequence of the will to live.

I scarcely need to draw attention to the fact that the considerations with which we now conclude the second book already point forcibly to the serious theme of the fourth book, indeed would pass over into it directly if it were not that my architectonic symmetry makes it necessary that the third book, with its fair contents, should come between, as a second consideration of the world as idea, the conclusion of which, however, again points in the same direction.

Supplements to the Third Book.

"Et is similis spectatori est, quad ab omni separatus spectaculum videt."
— Oupnekhat, vol. i. p. 304.

Chapter XXIX.[9] On The Knowledge Of The Ideas.

The intellect, which has hitherto only been considered in its original and natural condition of servitude under the will, appears in the third book in its deliverance from that bondage; with regard to which, however, it must at once be observed that we have not to do here with a lasting emancipation, but only with a brief hour of rest, an exceptional and indeed only momentary release from the service of the will. As this subject has been treated with sufficient fulness in the first volume, I have here only to add a few supplementary remarks.

As, then, was there explained, the intellect in its activity in the service of the will, thus in its natural function, knows only the mere relations of things; primarily to the will itself, to which it belongs, whereby they become motives of the will; but then also, just for the sake of the completeness of this knowledge, the relations of things to each other. This last knowledge first appears in some extent and importance in the human intellect; in the case of the brutes, on the other hand, even where the intellect is considerably developed, only within very narrow limits. Clearly even the apprehension of the relations which things have to each other only takes place, indirectly, in the service of the will. It therefore forms the transition to the purely objective knowledge, which is entirely independent of the will; it is scientific knowledge, the latter is artistic knowledge. If many and various relations of an object are immediately apprehended, from these the peculiar and proper nature of the object appears ever more distinctly, and gradually constructs itself out of mere relations: although it itself is entirely different from them. In this mode of apprehension the subjection of the intellect to the will at once becomes ever more indirect and less. If the intellect has strength enough to gain the preponderance, and let go altogether the relations of things to the will, in order to apprehend, instead of them, the purely objective nature of a phenomenon, which expresses itself through all relations, it also forsakes, along with the service of the will, the apprehension of mere relations, and thereby really also that of the individual thing as such. It then moves freely, no longer belonging to a will. In the individual thing it knows only the essential, and therefore its whole species; consequently it now has for its object the Ideas, in my sense, which agrees with the original, Platonic meaning of this grossly misused

word; thus the permanent, unchanging forms, independent of the temporal existence of the individuals, the species rerum, which really constitute what is purely objective in the phenomena. An Idea so apprehended is not yet indeed the essence of the thing in itself, just because it has sprung from knowledge of mere relations; yet, as the result of the sum of all the relations, it is the peculiar character of the thing, and thereby the complete expression of the essence which exhibits itself as an object of perception, comprehended, not in relation to an individual will, but as it expresses itself spontaneously, whereby indeed it determines all its relations, which till then alone were known. The Idea is the root point of all these relations, and thereby the complete and perfect phenomenon, or, as I have expressed it in the text, the adequate objectivity of the will at this grade of its manifestation. Form and colour, indeed, which in the apprehension of the Idea by perception are what is immediate, belong at bottom not to the Idea itself, but are merely the medium of its expression; for, strictly speaking, space is as foreign to it as time. In this sense the Neo-Platonist Olympiodorus already says in his commentary on Plato's Alcibiades (Kreuzer's edition of Proclus and Olympiodorus, vol. ii. p. 82): "το ειδος μεταδεδωκε μεν της μορφης τῃ ὑλῃ αμερες δε ον μετελαβεν εξ αυτης του δεαστατου:" *i.e.*, the Idea, in itself unextended, imparted certainly the form to the matter, but first assumed extension from it. Thus, as was said, the Ideas reveal not the thing in itself, but only the objective character of things, thus still only the phenomenon; and we would not even understand this character if the inner nature of things were not otherwise known to us at least obscurely and in feeling. This nature itself cannot be understood from the Ideas, nor in general through any merely objective knowledge; therefore it would remain an eternal secret if we were not able to approach it from an entirely different side. Only because every knowing being is also an individual, and thereby a part of nature, does the approach to the inner being of nature stand open to him in his own self-consciousness, where, as we have found, it makes itself known in the most immediate manner as will.

Now what the Platonic Idea is, regarded as a merely objective image, mere form, and thereby lifted out of time and all relations — that, taken empirically and in time, is the species or kind. This, then, is the empirical correlative of the Idea. The Idea is properly eternal, but the species is of endless duration, although its appearance upon one planet may become extinct. Even the names of the two pass over into each other: ιδεα, ειδος,

species, kind. The Idea is the species, but not the genus: therefore the species are the work of nature, the genera the work of man; they are mere conceptions. There are species naturales, but only genera logica. Of manufactured articles there are no Ideas, but only conceptions; thus genera logica, and their subordinate classes are species logicæ. To what is said in this reference in vol. i. § 41, I will add here that Aristotle also (*Metaph.* i. 9 and xiii. 5) says that the Platonists admitted no ideas of manufactured articles: "ὁιον οικια, και δακτυλιος, ὡν ου φασιν ειναι ειδη" (Ut domus et annulus, quorum ideas dari negant). With which compare the Scholiast, p. 562, 563 of the Berlin quarto edition. Aristotle further says (*Metaph.* xi. 3): "αλλ ειπερ (Supple., ειδῃ εστι) επι των φυσει (εστι) διο δη ου κακως ὁ Πλατων εφη, ὁτι ειδη εστι ὁποσα φυσει" (Si quidem ideæ sunt, in iis sunt, quæ natura fiunt: propter quod non male Plato dixit, quod species eorum sunt, quæ natura sunt). On which the Scholiast remarks, p. 800: "και τουτο αρεσκει και αυτοις τοις τας ιδεας θεμενοις; των γαρ ὑπο τεχνης γινομενων ιδεας ειναι ουκ ελεγον, αλλα των ὑπο φυσεως" (Hoc etiam ipsis ideas statuentibus placet: non enim arte factorum ideas dari ajebant, sed natura procreatorum). For the rest, the doctrine of Ideas originated with the Pythagoreans, unless we distrust the assertion of Plutarch in the book, *De placitis philosophorum*, L. i. c. 3.

The individual is rooted in the species, and time in eternity. And as every individual is so only because it has the nature of its species in itself, so also it has only temporal existence because it is in eternity. In the following book a special chapter is devoted to the life of the species.

In § 49 of the first volume I have sufficiently brought out the difference between the Idea and the conception. Their resemblance, on the other hand, rests upon the following ground: The original and essential unity of an Idea becomes broken up into the multiplicity of individual things through the perception of the knowing individual, which is subject to sensuous and cerebral conditions. But that unity is then restored through the reflection of the reason, yet only in abstracto, as a concept, universale, which indeed is equal to the Idea in extension, but has assumed quite a different form, and has thereby lost its perceptible nature, and with this its thorough determinateness. In this sense (but in no other) we might, in the language of the Scholastics, describe the Ideas as universalia ante rem, the conceptions as universalia post rem. Between the two stand the individual things, the knowledge of which is possessed also by the brutes. Without doubt the

realism of the Scholastics arose from the confusion of the Platonic Ideas, to which, since they are also the species, an objective real being can certainly be attributed, with the mere concepts to which the Realists now wished to attribute such a being, and thereby called forth the victorious opposition of Nominalism.

Chapter XXX.[10] On The Pure Subject Of Knowledge.

The comprehension of an Idea, the entrance of it into our consciousness, is only possible by means of a change in us, which might also be regarded as an act of self-denial; for it consists in this, that knowledge turns away altogether from our own will, thus now leaves out of sight entirely the valuable pledge intrusted to it, and considers things as if they could never concern the will at all. For thus alone does knowledge become a pure mirror of the objective nature of things. Knowledge conditioned in this way must lie at the foundation of every genuine work of art as its origin. The change in the subject which is required for this cannot proceed from the will, just because it consists in the elimination of all volition; thus it can be no act of the will, *i.e.*, it cannot lie in our choice. On the contrary, it springs only from a temporary preponderance of the intellect over the will, or, physiologically considered, from a strong excitement of the perceptive faculty of the brain, without any excitement of the desires or emotions. To explain this somewhat more accurately I remind the reader that our consciousness has two sides; partly, it is a consciousness of our own selves, which is the will; partly a consciousness of other things, and as such primarily, knowledge, through perception, of the external world, the apprehension of objects. Now the more one side of the whole consciousness comes to the front, the more the other side withdraws. Accordingly, the consciousness of other things, thus knowledge of perception, becomes the more perfect, *i.e.*, the more objective, the less we are conscious of ourselves at the time. Here exists an actual antagonism. The more we are conscious of the object, the less we are conscious of the subject; the more, on the other hand, the latter occupies our consciousness, the weaker and more imperfect is our perception of the external world. The state which is required for pure objectivity of perception has partly permanent conditions in the perfection of the brain and the general physiological qualities favourable to its activity, partly temporary conditions, inasmuch as such a state is favoured by all that increases the attention and heightens the susceptibility of the cerebral nervous system, yet without exciting any passion. One must not think here of spirituous drinks or opium; what is rather required is a night of quiet sleep, a cold bath, and all that procures for the brain activity an unforced predominance by quieting the circulation and

calming the passions. It is especially these natural means of furthering the cerebral nervous activity which bring it about, certainly so much the better the more developed and energetic in general the brain is, that the object separates itself ever more from the subject, and finally introduces the state of pure objectivity of perception, which of itself eliminates the will from consciousness, and in which all things stand before us with increased clearness and distinctness, so that we are conscious almost only of them and scarcely at all of ourselves; thus our whole consciousness is almost nothing more than the medium through which the perceived object appears in the world as an idea. Thus it is necessary for pure, will-less knowledge that the consciousness of ourselves should vanish, since the consciousness of other things is raised to such a pitch. For we only apprehend the world in a purely objective manner when we no longer know that we belong to it; and all things appear the more beautiful the more we are conscious merely of them and the less we are conscious of ourselves. Since now all suffering proceeds from the will, which constitutes the real self, with the withdrawal of this side of consciousness all possibility of suffering is also abolished; therefore the condition of the pure objectivity of perception is one which throughout gives pleasure; and hence I have shown that in it lies one of the two constituent elements of æsthetic satisfaction. As soon, on the other hand, as the consciousness of our own self, thus subjectivity, *i.e.*, the will, again obtains the upper hand, a proportional degree of discomfort or unrest also enters; of discomfort, because our corporealness (the organism which in itself is the will) is again felt; of unrest, because the will, on the path of thought, again fills the consciousness through wishes, emotions, passions, and cares. For the will, as the principle of subjectivity, is everywhere the opposite, nay, the antagonist of knowledge. The greatest concentration of subjectivity consists in the act of will proper, in which therefore we have the most distinct consciousness of our own self. All other excitements of the will are only preparations for this; the act of will itself is for subjectivity what for the electric apparatus is the passing of the spark. Every bodily sensation is in itself an excitement of the will, and indeed oftener of the noluntas than of the voluntas. The excitement of the will on the path of thought is that which occurs by means of motives; thus here the subjectivity is awakened and set in play by the objectivity itself. This takes place whenever any object is apprehended no longer in a purely objective manner, thus without participation in it, but, directly or indirectly, excites desire or

aversion, even if it is only by means of a recollection, for then it acts as a motive in the widest sense of the word.

I remark here that abstract thinking and reading, which are connected with words, belong indeed in the wider sense to the consciousness of other things, thus to the objective employment of the mind; yet only indirectly, by means of conceptions. But the latter are the artificial product of the reason, and are therefore already a work of intention. Moreover, the will is the ruler of all abstract exercise of the mind, for, according to its aims, it imparts the direction, and also fixes the attention; therefore such mental activity is always accompanied by some effort; and this presupposes the activity of the will. Thus complete objectivity of consciousness does not exist with this kind of mental activity, as it accompanies the æsthetic apprehension, *i.e.*, the knowledge of the Ideas, as a condition.

In accordance with the above, the pure objectivity of perception, by virtue of which no longer the individual thing as such, but the Idea of its species is known, is conditioned by the fact that one is no longer conscious of oneself, but only of the perceived objects, so that one's own consciousness only remains as the supporter of the objective existence of these objects. What increases the difficulty of this state, and therefore makes it more rare, is, that in it the accident (the intellect) overcomes and annuls the substance (the will), although only for a short time. Here also lies the analogy and, indeed, the relationship of this with the denial of the will expounded at the end of the following book. Although knowledge, as was shown in the preceding book, is sprung from the will and is rooted in the manifestation of the will, the organism, yet it is just by the will that its purity is disturbed, as the flame is by the fuel and its smoke. It depends upon this that we can only apprehend the purely objective nature of things, the Ideas which appear in them, when we have ourselves no interest in them, because they stand in no relation to our will. From this, again, it arises that the Ideas of anything appeal to us more easily from a work of art than from reality. For what we behold only in a picture or in poetry stands outside all possibility of having any relation to our will; for in itself it exists only for knowledge and appeals immediately to knowledge alone. On the other hand, the apprehension of Ideas from reality assumes some measure of abstraction from our own volition, arising above its interests which demands a special power of the intellect. In a high degree, and for some duration, this belongs only to genius, which consists indeed in this, that a

greater measure of the power of knowledge exists than is required for the service of an individual will, and this surplus becomes free, and now comprehends the world without reference to the will. Thus that the work of art facilitates so greatly the apprehension of the Ideas, in which æsthetic satisfaction consists, depends not merely upon the fact that art, by giving prominence to what is essential and eliminating what is unessential, presents the things more distinctly and characteristically, but just as much on the fact that the absolute silence of the will, which is demanded for the purely objective comprehension of the nature of the things, is attained with the greatest certainty when the perceived object itself lies entirely outside the province of things which are capable of having a relation to the will, because it is nothing real, but a mere picture. Now this holds good, not only of the works of plastic and pictorial art, but also of poetry; the effect of which is also conditioned by indifferent, will-less, and thereby purely objective apprehension. It is exactly this which makes a perceived object picturesque, an event of actual life poetical; for it is only this that throws over the objects of the real world that magic gleam which in the case of sensibly perceived objects is called the picturesque, and in the case of those which are only perceived in imagination is called the poetical. If poets sing of the blithe morning, the beautiful evening, the still moonlight night, and many such things, the real object of their praise is, unknown to themselves, the pure subject of knowledge which is called forth by those beauties of nature, and on the appearance of which the will vanishes from consciousness, and so that peace of heart enters which, apart from this, is unattainable in the world. How otherwise, for example, could the verse —

> "Nox erat, at cœlo fulgebat luna sereno,
> Inter minora sidera,"

affect us so beneficently, nay, so magically? Further, that the stranger or the mere passing traveller feels the picturesque or poetical effect of objects which are unable to produce this effect upon those who live among them may be explained from the fact that the novelty and complete strangeness of the objects of such an indifferent, purely objective apprehension are favourable to it. Thus, for example, the sight of an entirely strange town often makes a specially agreeable impression upon the traveller, which it by no means produces in the inhabitant of it; for it arises from the fact that the former, being out of all relation to this town and its inhabitants, perceives it

purely objectively. Upon this depends partly the pleasure of travelling. This seems also to be the reason why it is sought to increase the effect of narrative or dramatic works by transferring the scene to distant times or lands: in Germany, to Italy or Spain; in Italy, to Germany, Poland, or even Holland. If now perfectly objective, intuitive apprehension, purified from all volition, is the condition of the enjoyment of æsthetic objects, so much the more is it the condition of their production. Every good picture, every genuine poem, bears the stamp of the frame of mind described. For only what has sprung from perception, and indeed from purely objective perception, or is directly excited by it, contains the living germ from which genuine and original achievements can grow up: not only in plastic and pictorial art, but also in poetry, nay, even in philosophy. The punctum saliens of every beautiful work, of every great or profound thought, is a purely objective perception. Such perception, however, is absolutely conditioned by the complete silence of the will, which leaves the man simply the pure subject of knowledge. The natural disposition for the predominance of this state is genius.

With the disappearance of volition from consciousness, the individuality also, and with it its suffering and misery, is really abolished. Therefore I have described the pure subject of knowledge which then remains over as the eternal eye of the world, which, although with very different degrees of clearness, looks forth from all living creatures, untouched by their appearing and passing away, and thus, as identical with itself, as constantly one and the same, is the supporter of the world of permanent Ideas, *i.e.*, of the adequate objectivity of the will; while the individual subject, whose knowledge is clouded by the individuality which springs from the will, has only particular things as its object, and is transitory as these themselves. In the sense here indicated a double existence may be attributed to every one. As will, and therefore as individual, he is only one, and this one exclusively, which gives him enough to do and to suffer. As the purely objective perceiver, he is the pure subject of knowledge in whose consciousness alone the objective world has its existence; as such he is all things so far as he perceives them. and in him is their existence without burden or inconvenience. It is his existence, so far as it exists in his idea; but it is there without will. So far, on the other hand, as it is will, it is not in him. It is well with every one when he is in that state in which he is all things; it is ill with him when in the state in which he is exclusively one. Every state, every

man, every scene of life, requires only to be purely objectively apprehended and be made the subject of a sketch, whether with pencil or with words, in order to appear interesting, charming, and enviable; but if one is in it, if one is it oneself, then (it is often a case of) may the devil endure it. Therefore Goethe says —

"What in life doth only grieve us,
That in art we gladly see."

There was a period in the years of my youth when I was always trying to see myself and my action from without, and picture it to myself; probably in order to make it more enjoyable to me.

As I have never spoken before on the subject I have just been considering, I wish to add a psychological illustration of it.

In the immediate perception of the world and of life we consider things, as a rule, merely in their relations, consequently according to their relative and not their absolute nature and existence. For example, we will regard houses, ships, machines, and the like with the thought of their end and their adaptation to it; men, with the thought of their relation to us, if they have any such; and then with that of their relations to each other, whether in their present action or with regard to their position and business, judging perhaps their fitness for it, &c. Such a consideration of the relations we can follow more or less far to the most distant links of their chain: the consideration will thereby gain in accuracy and extent, but in its quality and nature it remains the same. It is the consideration of things in their relations, nay, by means of these, thus according to the principle of sufficient reason. Every one, for the most part and as a rule, is given up to this method of consideration; indeed I believe that most men are capable of no other. But if, as an exception, it happens that we experience a momentary heightening of the intensity of our intuitive intelligence, we at once see things with entirely different eyes, in that we now apprehend them no longer according to their relations, but according to that which they are in and for themselves, and suddenly perceive their absolute existence apart from their relative existence. At once every individual represents its species; and accordingly we now apprehend the universal of every being. Now what we thus know are the Ideas of things; but out of these there now speaks a higher wisdom than that which knows of mere relations. And we also have then passed out of the relations, and have thus become the pure subject of knowledge. But

what now exceptionally brings about this state must be internal physiological processes, which purify the activity of the brain, and heighten it to such a degree that a sudden spring-tide of activity like this ensues. The external conditions of this are that we remain completely strange to the scene to be considered, and separated from it, and are absolutely not actively involved in it.

In order to see that a purely objective, and therefore correct, comprehension of things is only possible when we consider them without any personal participation in them, thus when the will is perfectly silent, let one call to mind how much every emotion or passion disturbs and falsifies our knowledge, indeed how every inclination and aversion alters, colours, and distorts not only the judgment, but even the original perception of things. Let one remember how when we are gladdened by some fortunate occurrence the whole world at once assumes a bright colour and a smiling aspect, and, on the contrary, looks gloomy and sad when we are pressed with cares; also, how even a lifeless thing, if it is to be made use of in doing something which we abhor, seems to have a hideous physiognomy; for example, the scaffold, the fortress, to which we have been brought, the surgeon's cases of instruments; the travelling carriage of our loved one, &c., nay, numbers, letters, seals, may seem to grin upon us horribly and affect us as fearful monstrosities. On the other hand, the tools for the accomplishment of our wishes at once appear to us agreeable and pleasing; for example, the hump-backed old woman with the love-letter, the Jew with the louis d'ors, the rope-ladder to escape by, &c. As now here the falsification of the idea through the will in the case of special abhorrence or love is unmistakable, so is it present in a less degree in every object which has any even distant relation to our will, that is, to our desire or aversion. Only when the will with its interests has left consciousness, and the intellect freely follows its own laws, and as pure subject mirrors the objective world, yet in doing so, although spurred on by no volition, is of its own inclination in the highest state of tension and activity, do the colours and forms of things appear in their true and full significance. Thus it is from such comprehension alone that genuine works of art can proceed whose permanent worth and ever renewed approval arises simply from the fact that they express the purely objective element, which lies at the foundation of and shines through the different subjective, and therefore distorted, perceptions, as that which is common to them all and alone stands fast; as it

were the common theme of all those subjective variations. For certainly the nature which is displayed before our eyes exhibits itself very differently in different minds; and as each one sees it so alone can he repeat it, whether with the pencil or the chisel, or with words and gestures on the stage. Objectivity alone makes one capable of being an artist; but objectivity is only possible in this way, that the intellect, separated from its root the will, moves freely, and yet acts with the highest degree of energy.

To the youth whose perceptive intellect still acts with fresh energy nature often exhibits itself with complete objectivity, and therefore with perfect beauty. But the pleasure of such a glance is sometimes disturbed by the saddening reflection that the objects present which exhibit themselves in such beauty do not stand in a personal relation to this will, by virtue of which they could interest and delight him; he expects his life in the form of an interesting romance. "Behind that jutting cliff the well-mounted band of friends should await me, — beside that waterfall my love should rest; this beautifully lighted building should be her dwelling, and that vine-clad window hers; — but this beautiful world is for me a desert!" and so on. Such melancholy youthful reveries really demand something exactly contradictory to themselves; for the beauty with which those objects present themselves depends just upon the pure objectivity, *i.e.*, disinterestedness of their perception, and would therefore at once be abolished by the relation to his own will which the youth painfully misses, and thus the whole charm which now affords him pleasure, even though alloyed with a certain admixture of pain, would cease to exist. The same holds good, moreover, of every age and every relation; the beauty of the objects of a landscape which now delights us would vanish if we stood in personal relations to them, of which we remained always conscious. Everything is beautiful only so long as it does not concern us. (We are not speaking here of sensual passion, but of æsthetic pleasure.) Life is never beautiful, but only the pictures of life are so in the transfiguring mirror of art or poetry; especially in youth, when we do not yet know it. Many a youth would receive great peace of mind if one could assist him to this knowledge.

Why has the sight of the full moon such a beneficent, quieting, and exalting effect? Because the moon is an object of perception, but never of desire:

"The stars we yearn not after
Delight us with their glory." — G.

Further, it is sublime, *i.e.*, it induces a lofty mood in us, because, without any relation to us, it moves along for ever strange to earthly doings, and sees all while it takes part in nothing. Therefore, at the sight of it the will, with its constant neediness, vanishes from consciousness, and leaves a purely knowing consciousness behind. Perhaps there is also mingled here a feeling that we share this sight with millions, whose individual differences are therein extinguished, so that in this perception they are one, which certainly increases the impression of the sublime. Finally, this is also furthered by the fact that the moon lights without heating, in which certainly lies the reason why it has been called chaste and identified with Diana. In consequence of this whole beneficent impression upon our feeling, the moon becomes gradually our bosom friend. The sun, again, never does so; but is like an over-plenteous benefactor whom we can never look in the face.

The following remark may find room here as an addition to what is said in § 38 of the first volume on the æsthetic pleasure afforded by light, reflection, and colours. The whole immediate, thoughtless, but also unspeakable, pleasure which is excited in us by the impression of colours, strengthened by the gleam of metal, and still more by transparency, as, for example, in coloured windows, and in a greater measure by means of the clouds and their reflection at sunset, — ultimately depends upon the fact that here in the easiest manner, almost by a physical necessity, our whole interest is won for knowledge, without any excitement of our will, so that we enter the state of pure knowing, although for the most part this consists here in a mere sensation of the affection of the retina, which, however, as it is in itself perfectly free from pain or pleasure, and therefore entirely without direct influence on the will, thus belongs to pure knowledge.

Chapter XXXI.[11] On Genius.

What is properly denoted by the name genius is the predominating capacity for that kind of knowledge which has been described in the two preceding chapters, the knowledge from which all genuine works of art and poetry, and even of philosophy, proceed. Accordingly, since this has for its objects the Platonic Ideas, and these are not comprehended in the abstract, but only perceptibly, the essence of genius must lie in the perfection and energy of the knowledge of perception. Corresponding to this, the works which we hear most decidedly designated works of genius are those which start immediately from perception and devote themselves to perception; thus those of plastic and pictorial art, and then those of poetry, which gets its perceptions by the assistance of the imagination. The difference between genius and mere talent makes itself noticeable even here. For talent is an excellence which lies rather in the greater versatility and acuteness of discursive than of intuitive knowledge. He who is endowed with talent thinks more quickly and more correctly than others; but the genius beholds another world from them all, although only because he has a more profound perception of the world which lies before them also, in that it presents itself in his mind more objectively, and consequently in greater purity and distinctness.

The intellect is, according to its destination, merely the medium of motives; and in accordance with this it originally comprehends nothing in things but their relations to the will, the direct, the indirect, and the possible. In the case of the brutes, where it is almost entirely confined to the direct relations, the matter is just on that account most apparent: what has no relation to their will does not exist for them. Therefore we sometimes see with surprise that even clever animals do not observe at all something conspicuous to them; for example, they show no surprise at obvious alterations in our person and surroundings. In the case of normal men the indirect, and even the possible, relations to the will are added, the sum of which make up the total of useful knowledge; but here also knowledge remains confined to the relations. Therefore the normal mind does not attain to an absolutely pure, objective picture of things, because its power of perception, whenever it is not spurred on by the will and set in motion, at

once becomes tired and inactive, because it has not enough energy of its own elasticity and without an end in view to apprehend the world in a purely objective manner. Where, on the other hand, this takes place — where the brain has such a surplus of the power of ideation that a pure, distinct, objective image of the external world exhibits itself without any aim; an image which is useless for the intentions of the will, indeed, in the higher degrees, disturbing, and even injurious to them — there, the natural disposition, at least, is already present for that abnormity which the name genius denotes, which signifies that here a genius foreign to the will, *i.e.*, to the I proper, as it were coming from without, seems to be active. But to speak without a figure: genius consists in this, that the knowing faculty has received a considerably greater development than the service of the will, for which alone it originally appeared, demands. Therefore, strictly speaking, physiology might to a certain extent class such a superfluity of brain activity, and with it of brain itself, among the monstra per excessum, which, it is well known, it co-ordinates with monstra per defectum and those per situm mutatum. Thus genius consists in an abnormally large measure of intellect, which can only find its use by being applied to the universal of existence, whereby it then devotes itself to the service of the whole human race, as the normal intellect to that of the individual. In order to make this perfectly comprehensible one might say: if the normal man consists of two-thirds will and one-third intellect, the genius, on the contrary, has two-thirds intellect and one-third will. This might, then, be further illustrated by a chemical simile: the base and the acid of a neutral salt are distinguished by the fact that in each of the two the radical has the converse relation to oxygen to that which it has in the other. The base or the alkali is so because in it the radical predominates with reference to oxygen, and the acid is so because in it oxygen predominates. In the same way now the normal man and the genius are related in respect of will and intellect. From this arises a thorough distinction between them, which is visible even in their whole nature and behaviour, but comes out most clearly in their achievements. One might add the difference that while that total opposition between the chemical materials forms the strongest affinity and attraction between them, in the human race the opposite is rather wont to be found.

The first manifestation which such a superfluity of the power of knowledge calls forth shows itself for the most part in the most original and fundamental knowledge, *i.e.*, in knowledge of perception, and occasions the

repetition of it in an image; hence arises the painter and the sculptor. In their case, then, the path between the apprehension of genius and the artistic production is the shortest; therefore the form in which genius and its activity here exhibits itself is the simplest and its description the easiest. Yet here also the source is shown from which all genuine productions in every art, in poetry, and indeed in philosophy, have their origin, although in the case of these the process is not so simple.

Let the result arrived at in the first book be here borne in mind, that all perception is intellectual and not merely sensuous. If one now adds the exposition given here, and, at the same time, in justice considers that the philosophy of last century denoted the perceptive faculty of knowledge by the name "lower powers of the soul," we will not think it so utterly absurd nor so deserving of the bitter scorn with which Jean Paul quotes it in his "*Vorschule der Æsthetik*," that Adelung, who had to speak the language of his age, placed genius in "a remarkable strength of the lower powers of the soul." The work just referred to of this author, who is so worthy of our admiration, has great excellences, but yet I must remark that all through, whenever a theoretical explanation and, in general, instruction is the end in view, a style of exposition which is constantly indulging in displays of wit and hurrying along in mere similes cannot be well adapted to the purpose.

It is, then, perception to which primarily the peculiar and true nature of things, although still in a conditioned manner, discloses and reveals itself. All conceptions and everything thought are mere abstractions, consequently partial ideas taken from perception, and have only arisen by thinking away. All profound knowledge, even wisdom properly so called, is rooted in the perceptive apprehension of things, as we have fully considered in the supplements to the first book. A perceptive apprehension has always been the generative process in which every genuine work of art, every immortal thought, received the spark of life. All primary thought takes place in pictures. From conceptions, on the other hand, arise the works of mere talent, the merely rational thoughts, imitations, and indeed all that is calculated merely with reference to the present need and contemporary conditions.

But if now our perception were constantly bound to the real present of things, its material would be entirely under the dominion of chance, which seldom produces things at the right time, seldom arranges them for an end and for the most part presents them to us in very defective examples.

Therefore the imagination is required in order to complete, arrange, give the finishing touches to, retain, and repeat at pleasure all those significant pictures of life, according as the aims of a profoundly penetrating knowledge and of the significant work whereby they are to be communicated may demand. Upon this rests the high value of imagination, which is an indispensable tool of genius. For only by virtue of imagination can genius ever, according to the requirements of the connection of its painting or poetry or thinking, call up to itself each object or event in a lively image, and thus constantly draw fresh nourishment from the primary source of all knowledge, perception. The man who is endowed with imagination is able, as it were, to call up spirits, who at the right time reveal to him the truths which the naked reality of things exhibits only weakly, rarely, and then for the most part at the wrong time. Therefore the man without imagination is related to him, as the mussel fastened to its rock, which must wait for what chance may bring it, is related to the freely moving or even winged animal. For such a man knows nothing but the actual perception of the senses: till it comes he gnaws at conceptions and abstractions which are yet mere shells and husks, not the kernel of knowledge. He will never achieve anything great, unless it be in calculating and mathematics. The works of plastic and pictorial art and of poetry, as also the achievements of mimicry, may also be regarded as means by which those who have no imagination may make up for this defect as far as possible, and those who are gifted with it may facilitate the use of it.

Thus, although the kind of knowledge which is peculiar and essential to genius is knowledge of perception, yet the special object of this knowledge by no means consists of the particular things, but of the Platonic Ideas which manifest themselves in these, as their apprehension was analysed in chapter 29. Always to see the universal in the particular is just the fundamental characteristic of genius, while the normal man knows in the particular only the particular as such, for only as such does it belong to the actual which alone has interests for him, *i.e.*, relations to his will. The degree in which every one not merely thinks, but actually perceives, in the particular thing, only the particular, or a more or less universal up to the most universal of the species, is the measure of his approach to genius. And corresponding to this, only the nature of things generally, the universal in them, the whole, is the special object of genius. The investigation of the

particular phenomena is the field of the talents, in the real sciences, whose special object is always only the relations of things to each other.

What was fully shown in the preceding chapter, that the apprehension of the Ideas is conditioned by the fact that the knower is the pure subject of knowledge, *i.e.*, that the will entirely vanishes from consciousness, must be borne in mind here. The pleasure which we have in many of Goethe's songs which bring the landscape before our eyes, or in Jean Paul's sketches of nature, depends upon the fact that we thereby participate in the objectivity of those minds, *i.e.*, the purity with which in them the world as idea separated from the world as will, and, as it were, entirely emancipated itself from it. It also follows from the fact that the kind of knowledge peculiar to genius is essentially that which is purified from all will and its relations, that the works of genius do not proceed from intention or choice, but it is guided in them by a kind of instinctive necessity. What is called the awaking of genius, the hour of initiation, the moment of inspiration, is nothing but the attainment of freedom by the intellect, when, delivered for a while from its service under the will, it does not now sink into inactivity or lassitude, but is active for a short time entirely alone and spontaneously. Then it is of the greatest purity, and becomes the clear mirror of the world; for, completely severed from its origin, the will, it is now the world as idea itself, concentrated in one consciousness. In such moments, as it were, the souls of immortal works are begotten. On the other hand, in all intentional reflection the intellect is not free, for indeed the will guides it and prescribes it its theme.

The stamp of commonness, the expression of vulgarity, which is impressed on the great majority of countenances consists really in this, that in them becomes visible the strict subordination of their knowledge to their will, the firm chain which binds these two together, and the impossibility following from this of apprehending things otherwise than in their relation to the will and its aims. On the other hand, the expression of genius which constitutes the evident family likeness of all highly gifted men consists in this, that in it we distinctly read the liberation, the manumission of the intellect from the service of the will, the predominance of knowledge over volition; and because all anxiety proceeds from the will, and knowledge, on the contrary, is in and for itself painless and serene, this gives to their lofty brow and clear, perceiving glance, which are not subject to the service of the will and its wants, that look of great, almost supernatural serenity which

at times breaks through, and consists very well with the melancholy of their other features, especially the mouth, and which in this relation may be aptly described by the motto of Giordano Bruno: In tristitia hilaris, in hilaritate tristis.

The will, which is the root of the intellect, opposes itself to any activity of the latter which is directed to anything else but its own aims. Therefore the intellect is only capable of a purely objective and profound comprehension of the external world when it has freed itself at least for a while from this its root. So long as it remains bound to the will, it is of its own means capable of no activity, but sleeps in a stupor, whenever the will (the interests) does not awake it, and set it in motion. If, however, this happens, it is indeed very well fitted to recognise the relations of things according to the interest of the will, as the prudent mind does, which, however, must always be an awakened mind, *i.e.*, a mind actively aroused by volition; but just on this account it is not capable of comprehending the purely objective nature of things. For the willing and the aims make it so one-sided that it sees in things only that which relates to these, and the rest either disappears or enters consciousness in a falsified form. For example, the traveller in anxiety and haste will see the Rhine and its banks only as a line, and the bridges over it only as lines cutting it. In the mind of the man who is filled with his own aims the world appears as a beautiful landscape appears on the plan of a battlefield. Certainly these are extremes, taken for the sake of distinctness; but every excitement of the will, however slight, will have as its consequence a slight but constantly proportionate falsification of knowledge. The world can only appear in its true colour and form, in its whole and correct significance, when the intellect, devoid of willing, moves freely over the objects, and without being driven on by the will is yet energetically active. This is certainly opposed to the nature and determination of the intellect, thus to a certain extent unnatural, and just on this account exceedingly rare; but it is just in this that the essential nature of genius lies, in which alone that condition takes place in a high degree and is of some duration, while in others it only appears approximately and exceptionally. I take it to be in the sense expounded here that Jean Paul (*Vorschule der Æsthetik*, § 12) places the essence of genius in reflectiveness. The normal man is sunk in the whirl and tumult of life, to which he belongs through his will; his intellect is filled with the things and events of life; but he does not know these things nor life itself in their

objective significance; as the merchant on ’Change in Amsterdam apprehends perfectly what his neighbour says, but does not hear the hum of the whole Exchange, like the sound of the sea, which astonishes the distant observer. From the genius, on the contrary, whose intellect is delivered from the will, and thus from the person, what concerns these does not conceal the world and things themselves; but he becomes distinctly conscious of them, he apprehends them in and for themselves in objective perception; in this sense he is reflective.

It is reflectiveness which enables the painter to repeat the natural objects which he contemplates faithfully upon the canvas, and the poet accurately to call up again the concrete present, by means of abstract conceptions, by giving it utterance and so bringing it to distinct consciousness, and also to express everything in words which others only feel. The brute lives entirely without reflection. It has consciousness, *i.e.*, it knows itself and its good and ill, also the objects which occasion these. But its knowledge remains always subjective, never becomes objective; everything that enters it seems a matter of course, and therefore can never become for it a theme (an object of exposition) nor a problem (an object of meditation). Its consciousness is thus entirely immanent. Not certainly the same, but yet of kindred nature, is the consciousness of the common type of man, for his apprehension also of things and the world is predominantly subjective and remains prevalently immanent. It apprehends the things in the world, but not the world; its own action and suffering, but not itself. As now in innumerable gradations the distinctness of consciousness rises, reflectiveness appears more and more; and thus it is brought about little by little that sometimes, though rarely, and then again in very different degrees of distinctness, the question passes through the mind like a flash, “What is all this?” or again, “How is it really fashioned?” The first question, if it attains great distinctness and continued presence, will make the philosopher, and the other, under the same conditions, the artist or the poet. Therefore, then, the high calling of both of these has its root in the reflectiveness which primarily springs from the distinctness with which they are conscious of the world and their own selves, and thereby come to reflect upon them. But the whole process springs from the fact that the intellect through its preponderance frees itself for a time from the will, to which it is originally subject.

The considerations concerning genius here set forth are connected by way of supplement with the exposition contained in chapter 21, of the ever

wider separation of the will and the intellect, which can be traced in the whole series of existences. This reaches its highest grade in genius, where it extends to the entire liberation of the intellect from its root the will, so that here the intellect becomes perfectly free, whereby the world as idea first attains to complete objectification.

A few remarks now concerning the individuality of genius. Aristotle has already said, according to Cicero (*Tusc.*, i. 33), "Omnes ingeniosos melancholicos esse;" which without doubt is connected with the passage of Aristotle's "*Problemata*," xxx. 1. Goethe also says: "My poetic rapture was very small, so long as I only encountered good; but it burnt with a bright flame when I fled from threatening evil. The tender poem, like the rainbow, is only drawn on a dark ground; hence the genius of the poet loves the element of melancholy."

This is to be explained from the fact that since the will constantly re-establishes its original sway over the intellect, the latter more easily withdraws from this under unfavourable personal relations; because it gladly turns from adverse circumstances, in order to a certain extent to divert itself, and now directs itself with so much the greater energy to the foreign external world, thus more easily becomes purely objective. Favourable personal relations act conversely. Yet as a whole and in general the melancholy which accompanies genius depends upon the fact that the brighter the intellect which enlightens the will to live, the more distinctly does it perceive the misery of its condition. The melancholy disposition of highly gifted minds which has so often been observed has its emblem in Mont Blanc, the summit of which is for the most part lost in clouds; but when sometimes, especially in the early morning, the veil of clouds is rent and now the mountain looks down on Chamounix from its height in the heavens above the clouds, then it is a sight at which the heart of each of us swells from its profoundest depths. So also the genius, for the most part melancholy, shows at times that peculiar serenity already described above, which is possible only for it, and springs from the most perfect objectivity of the mind. It floats like a ray of light upon his lofty brow: In tristitia hilaris, in hilaritate tristis.

All bunglers are so ultimately because their intellect, still too firmly bound to the will, only becomes active when spurred on by it, and therefore remains entirely in its service. They are accordingly only capable of personal aims. In conformity with these they produce bad pictures, insipid

poems, shallow, absurd, and very often dishonest philosophemes, when it is to their interest to recommend themselves to high authorities by a pious disingenuousness. Thus all their action and thought is personal. Therefore they succeed at most in appropriating what is external, accidental, and arbitrary in the genuine works of others as mannerisms, in doing which they take the shell instead of the kernel, and yet imagine they have attained to everything, nay, have surpassed those works. If, however, the failure is patent, yet many hope to attain success in the end through their good intentions. But it is just this good will which makes success impossible; because this only pursues personal ends, and with these neither art nor poetry nor philosophy can ever be taken seriously. Therefore the saying is peculiarly applicable to such persons: “They stand in their own light.” They have no idea that it is only the intellect delivered from the government of the will and all its projects, and therefore freely active, that makes one capable of genuine productions, because it alone imparts true seriousness; and it is well for them that they have not, otherwise they would leap into the water. The good will is in morality everything; but in art it is nothing. In art, as the word itself indicates (Kunst), what alone is of consequence is ability (Können). It all amounts ultimately to this, where the true seriousness of the man lies. In almost all it lies exclusively in their own well-being and that of their families; therefore they are in a position to promote this and nothing else; for no purpose, no voluntary and intentional effort, imparts the true, profound, and proper seriousness, or makes up for it, or more correctly, takes its place. For it always remains where nature has placed it; and without it everything is only half performed. Therefore, for the same reason, persons of genius often manage so badly for their own welfare. As a leaden weight always brings a body back to the position which its centre of gravity thereby determined demands, so the true seriousness of the man always draws the strength and attention of the intellect back to that in which it lies; everything else the man does without true seriousness. Therefore only the exceedingly rare and abnormal men whose true seriousness does not lie in the personal and practical, but in the objective and theoretical, are in a position to apprehend what is essential in the things of the world, thus the highest truths, and reproduce them in any way. For such a seriousness of the individual, falling outside himself in the objective, is something foreign to the nature of man, something unnatural, or really supernatural: yet on account of this alone is the man great; and therefore what he achieves is

then ascribed to a genius different from himself, which takes possession of him. To such a man his painting, poetry, or thinking is an end; to others it is a means. The latter thereby seek their own things, and, as a rule, they know how to further them, for they flatter their contemporaries, ready to serve their wants and humours; therefore for the most part they live in happy circumstances; the former often in very miserable circumstances. For he sacrifices his personal welfare to his objective end; he cannot indeed do otherwise, because his seriousness lies there. They act conversely; therefore they are small, but he is great. Accordingly his work is for all time, but the recognition of it generally only begins with posterity: they live and die with their time. In general he only is great who in his work, whether it is practical or theoretical, seeks not his own concerns, but pursues an objective end alone; he is so, however, even when in the practical sphere this end is a misunderstood one, and even if in consequence of this it should be a crime. That he seeks not himself and his own concerns, this makes him under all circumstances great. Small, on the other hand, is all action which is directed to personal ends; for whoever is thereby set in activity knows and finds himself only in his own transient and insignificant person. He who is great, again, finds himself in all, and therefore in the whole: he lives not, like others, only in the microcosm, but still more in the macrocosm. Hence the whole interests him, and he seeks to comprehend it in order to represent it, or to explain it, or to act practically upon it. For it is not strange to him; he feels that it concerns him. On account of this extension of his sphere he is called great. Therefore that lofty predicate belongs only to the true hero, in some sense, and to genius: it signifies that they, contrary to human nature, have not sought their own things, have not lived for themselves, but for all. As now clearly the great majority must constantly be small, and can never become great, the converse of this, that one should be great throughout, that is, constantly and every moment, is yet not possible —

"For man is made of common clay,
And custom is his nurse."

Every great man must often be only the individual, have only himself in view, and that means he must be small. Upon this depends the very true remark, that no man is a hero to his valet, and not upon the fact that the

valet cannot appreciate the hero; which Goethe, in the "*Wahlverwandhschaften*" (vol. ii. chap. 5), serves up as an idea of Ottilie's.

Genius is its own reward: for the best that one is, one must necessarily be for oneself. "Whoever is born with a talent, to a talent, finds in this his fairest existence," says Goethe. When we look back at a great man of former times, we do not think, "How happy is he to be still admired by all of us!" but, "How happy must he have been in the immediate enjoyment of a mind at the surviving traces of which centuries revive themselves!" Not in the fame, but in that whereby it is attained, lies the value, and in the production of immortal children the pleasure. Therefore those who seek to show the vanity of posthumous fame from the fact that he who obtains it knows nothing of it, may be compared to the wiseacre who very learnedly tried to demonstrate to the man who cast envious glances at a heap of oyster-shells in his neighbour's yard the absolute uselessness of them.

According to the exposition of the nature of genius which has been given, it is so far contrary to nature, inasmuch as it consists in this, that the intellect, whose real destination is the service of the will, emancipates itself from this service in order to be active on its own account. Accordingly genius is an intellect which has become untrue to its destination. Upon this depend the disadvantages connected with it, for the consideration of which we shall now prepare the way by comparing genius with the less decided predominance of the intellect.

The intellect of the normal man, strictly bound to the service of the will, and therefore really only occupied with the apprehension of motives, may be regarded as a complex system of wires, by means of which each of these puppets is set in motion in the theatre of the world. From this arises the dry, grave seriousness of most people, which is only surpassed by that of the brutes, who never laugh. On the other hand, we might compare the genius, with his unfettered intellect, to a living man playing along with the large puppets of the famous puppet-show at Milan, who would be the only one among them who would understand everything, and would therefore gladly leave the stage for a while to enjoy the play from the boxes; — that is the reflectiveness of genius. But even the man of great understanding and reason, whom one might almost call wise, is very different from the genius, and in this way, that his intellect retains a practical tendency, is concerned with the choice of the best ends and means, therefore remains in the service of the will, and accordingly is occupied in a manner that is thoroughly in

keeping with nature. The firm, practical seriousness of life which the Romans denoted gravitas presupposes that the intellect does not forsake the service of the will in order to wander away after that which does not concern the will; therefore it does not admit of that separation of the will and the intellect which is the condition of genius. The able, nay, eminent man, who is fitted for great achievements in the practical sphere, is so precisely because objects rouse his will in a lively manner, and spur him on to the ceaseless investigation of their relations and connections. Thus his intellect has grown up closely connected with his will. Before the man of genius, on the contrary, there floats in his objective comprehension the phenomenon of the world, as something foreign to him, an object of contemplation, which expels his will from consciousness. Round this point turns the distinction between the capacity for deeds and for works. The latter demand objectivity and depth of knowledge, which presupposes entire separation of the intellect from the will; the former, on the other hand, demands the application of knowledge, presence of mind, and decision, which required that the intellect should uninterruptedly attend to the service of the will. Where the bond between the intellect and the will is loosened, the intellect, turned away from its natural destination, will neglect the service of the will; it will, for example, even in the need of the moment, preserve its emancipation, and perhaps be unable to avoid taking in the picturesque impression of the surroundings, from which danger threatens the individual. The intellect of the reasonable and understanding man, on the other hand, is constantly at its post, is directed to the circumstances and their requirements. Such a man will therefore in all cases determine and carry out what is suitable to the case, and consequently will by no means fall into those eccentricities, personal slips, nay, follies, to which the genius is exposed, because his intellect does not remain exclusively the guide and guardian of his will, but sometimes more, sometimes less, is laid claim to by the purely objective. In the contrast of Tasso and Antonio, Goethe has illustrated the opposition, here explained in the abstract, in which these two entirely different kinds of capacity stand to each other. The kinship of genius and madness, so often observed, depends chiefly upon that separation of the intellect from the will which is essential to genius, but is yet contrary to nature. But this separation itself is by no means to be attributed to the fact that genius is accompanied by less intensity of will; for it is rather distinguished by a vehement and passionate character; but it is to

be explained from this, that the practically excellent person, the man of deeds, has merely the whole, full measure of intellect required for an energetic will while most men lack even this; but genius consists in a completely abnormal, actual superfluity of intellect, such as is required for the service of no will. On this account the men of genuine works are a thousand times rarer than the men of deeds. It is just that abnormal superfluity of intellect by virtue of which it obtains the decided preponderance, sets itself free from the will, and now, forgetting its origin, is freely active from its own strength and elasticity; and from this the creations of genius proceed.

Now further, just this, that genius in working consists of the free intellect, *i.e.*, of the intellect emancipated from the service of the will, has as a consequence that its productions serve no useful ends. The work of genius is music, or philosophy, or paintings, or poetry; it is nothing to use. To be of no use belongs to the character of the works of genius; it is their patent of nobility. All other works of men are for the maintenance or easing of our existence; only those we are speaking of are not; they alone exist for their own sake, and are in this sense to be regarded as the flower or the net profit of existence. Therefore our heart swells at the enjoyment of them, for we rise out of the heavy earthly atmosphere of want. Analogous to this, we see the beautiful, even apart from these, rarely combined with the useful. Lofty and beautiful trees bear no fruit; the fruit-trees are small, ugly cripples. The full garden rose is not fruitful, but the small, wild, almost scentless roses are. The most beautiful buildings are not the useful ones; a temple is no dwelling-house. A man of high, rare mental endowments compelled to apply himself to a merely useful business, for which the most ordinary man would be fitted, is like a costly vase decorated with the most beautiful painting which is used as a kitchen pot; and to compare useful people with men of genius is like comparing building-stone with diamonds.

Thus the merely practical man uses his intellect for that for which nature destined it, the comprehension of the relations of things, partly to each other, partly to the will of the knowing individual. The genius, on the other hand, uses it, contrary to its destination, for the comprehension of the objective nature of things. His mind, therefore, belongs not to himself, but to the world, to the illumination of which, in some sense, it will contribute. From this must spring manifold disadvantages to the individual favoured with genius. For his intellect will in general show those faults which are

rarely wanting in any tool which is used for that for which it has not been made. First of all, it will be, as it were, the servant of two masters, for on every opportunity it frees itself from the service to which it was destined in order to follow its own ends, whereby it often leaves the will very inopportunely in a fix, and thus the individual so gifted becomes more or less useless for life, nay, in his conduct sometimes reminds us of madness. Then, on account of its highly developed power of knowledge, it will see in things more the universal than the particular; while the service of the will principally requires the knowledge of the particular. But, again, when, as opportunity offers, that whole abnormally heightened power of knowledge directs itself with all its energy to the circumstances and miseries of the will, it will be apt to apprehend these too vividly, to behold all in too glaring colours, in too bright a light, and in a fearfully exaggerated form, whereby the individual falls into mere extremes. The following may serve to explain this more accurately. All great theoretical achievements, in whatever sphere they may be, are brought about in this way: Their author directs all the forces of his mind upon one point, in which he lets them unite and concentrate so strongly, firmly, and exclusively that now the whole of the rest of the world vanishes for him, and his object fills all reality. Now this great and powerful concentration which belongs to the privileges of genius sometimes appears for it also in the case of objects of the real world and the events of daily life, which then, brought under such a focus, are magnified to such a monstrous extent that they appear like the flea, which under the solar microscope assumes the stature of an elephant. Hence it arises that highly gifted individuals sometimes are thrown by trifles into violent emotions of the most various kinds, which are incomprehensible to others, who see them transported with grief, joy, care, fear, anger, &c., by things which leave the every-day man quite composed. Thus, then, the genius lacks soberness, which simply consists in this, that one sees in things nothing more than actually belongs to them, especially with reference to our possible ends; therefore no sober-minded man can be a genius. With the disadvantages which have been enumerated there is also associated hyper-sensibility, which an abnormally developed nervous and cerebral system brings with it, and indeed in union with the vehemence and passionateness of will which is certainly characteristic of genius, and which exhibits itself physically as energy of the pulsation of the heart. From all this very easily arises that extravagance of disposition, that vehemence of the emotions, that

quick change of mood under prevailing melancholy, which Goethe has presented to us in Tasso. What reasonableness, quiet composure, finished surveyal, certainty and proportionateness of behaviour is shown by the well-endowed normal man in comparison with the now dreamy absentness, and now passionate excitement of the man of genius, whose inward pain is the mother's lap of immortal works! To all this must still be added that genius lives essentially alone. It is too rare to find its like with ease, and too different from the rest of men to be their companion. With them it is the will, with him it is knowledge, that predominates; therefore their pleasures are not his, and his are not theirs. They are merely moral beings, and have merely personal relations; he is at the same time a pure intellect, and as such belongs to the whole of humanity. The course of thought of the intellect which is detached from its mother soil, the will, and only returns to it periodically, will soon show itself entirely different from that of the normal intellect, still cleaving to its stem. For this reason, and also on account of the dissimilarity of the pace, the former is not adapted for thinking in common, *i.e.*, for conversation with the others: they will have as little pleasure in him and his oppressive superiority as he will in them. They will therefore feel more comfortable with their equals, and he will prefer the entertainment of his equals, although, as a rule, this is only possible through the works they have left behind them. Therefore Chamfort says very rightly: "Il y a peu de vices qui empêchent un homme d'avoir beaucoup d'amis, autant que peuvent le faire de trop grandes qualités." The happiest lot that can fall to the genius is release from action, which is not his element, and leisure for production. From all this it results that although genius may highly bless him who is gifted with it, in the hours in which, abandoned to it, he revels unhindered in its delight, yet it is by no means fitted to procure for him a happy course of life; rather the contrary. This is also confirmed by the experience recorded in biographies. Besides this there is also an external incongruity, for the genius, in his efforts and achievements themselves, is for the most part in contradiction and conflict with his age. Mere men of talent come always at the right time; for as they are roused by the spirit of their age, and called forth by its needs, they are also capable only of satisfying these. They therefore go hand in hand with the advancing culture of their contemporaries or with the gradual progress of a special science: for this they reap reward and approval. But to the next generation their works are no longer enjoyable; they must be replaced by others, which again are

not permanent. The genius, on the contrary, comes into his age like a comet into the paths of the planets, to whose well-regulated and comprehensible order its entirely eccentric course is foreign. Accordingly he cannot go hand in hand with the existing, regular progress of the culture of the age, but flings his works far out on to the way in front (as the dying emperor flung his spear among the enemy), upon which time has first to overtake them. His relation to the culminating men of talent of his time might be expressed in the words of the Evangelist: "Ὁ καιρος ὁ εμος ουπω παρεστιν; ὁ δε καιρος ὁ ὑμετερος παντοτε εστιν ἑτοιμος" (John vii. 6). The man of talent can achieve what is beyond the power of achievement of other men, but not what is beyond their power of apprehension: therefore he at once finds those who prize him. But the achievement of the man of genius, on the contrary, transcends not only the power of achievement, but also the power of apprehension of others; therefore they do not become directly conscious of him. The man of talent is like the marksman who hits a mark the others cannot hit; the man of genius is like the marksman who hits a mark they cannot even see to; therefore they only get news of him indirectly, and thus late; and even this they only accept upon trust and faith. Accordingly Goethe says in one of his letters, "Imitation is inborn in us; what to imitate is not easily recognised. Rarely is what is excellent found; still more rarely is it prized." And Chamfort says: "Il en est de la valeur des hommes comme de celle des diamans, qui à une certaine mesure de grosseur, de pureté, de perfection, ont un prix fixe et marqué, mais qui, par-delà cette mesure, restent sans prix, et ne trouvent point d'acheteurs." And Bacon of Verulam has also expressed it: "Infimarum virtutum, apud vulgus, laus est, mediarum admiratio, supremarum sensus nullus" (*De augm. sc.*, L. vi. c. 3). Indeed, one might perhaps reply, Apud vulgus! But I must then come to his assistance with Machiavelli's assurance: "Nel mondo non è se non volgo;"[12] as also Thilo (*Ueber den Ruhm*) remarks, that to the vulgar herd there generally belongs one more than each of us believes. It is a consequence of this late recognition of the works of the man of genius that they are rarely enjoyed by their contemporaries, and accordingly in the freshness of colour which synchronism and presence imparts, but, like figs and dates, much more in a dry than in a fresh state.

If, finally, we consider genius from the somatic side, we find it conditioned by several anatomical and physiological qualities, which

individually are seldom present in perfection, and still more seldom perfect together, but which are yet all indispensably required; so that this explains why genius only appears as a perfectly isolated and almost portentous exception. The fundamental condition is an abnormal predominance of sensibility over irritability and reproductive power; and what makes the matter more difficult, this must take place in a male body. (Women may have great talent, but no genius, for they always remain subjective.) Similarly the cerebral system must be perfectly separated from the ganglion system by complete isolation, so that it stands in complete opposition to the latter; and thus the brain pursues its parasitic life on the organism in a very decided, isolated, powerful, and independent manner. Certainly it will thereby very easily affect the rest of the organism injuriously, and through its heightened life and ceaseless activity wear it out prematurely, unless it is itself possessed of energetic vital force and a good constitution: thus the latter belong to the conditions of genius. Indeed even a good stomach is a condition on account of the special and close agreement of this part with the brain. But chiefly the brain must be of unusual development and magnitude, especially broad and high. On the other hand, its depth will be inferior, and the cerebrum will abnormally preponderate in proportion to the cerebellum. Without doubt much depends upon the configuration of the brain as a whole and in its parts; but our knowledge is not yet sufficient to determine this accurately, although we easily recognise the form of skull that indicates a noble and lofty intelligence. The texture of the mass of the brain must be of extreme fineness and perfection, and consist of the purest, most concentrated, tenderest, and most excitable nerve-substance; certainly the quantitative proportion of the white to the grey matter has a decided influence, which, however, we are also unable as yet to specify. However, the report of the post-mortem on the body of Byron[13] shows that in his case the white matter was in unusually large proportion to the grey, and also that his brain weighed six pounds. Cuvier's brain weighed five pounds; the normal weight is three pounds. In contrast to the superior size of the brain, the spinal cord and nerves must be unusually thin. A beautifully arched, high and broad skull of thin bone must protect the brain without in any way cramping it. This whole quality of the brain and nervous system is the inheritance from the mother, to which we shall return in the following book. But it is quite insufficient to produce the phenomenon of genius if the inheritance from the father is not added, a lively, passionate temperament,

which exhibits itself somatically as unusual energy of the heart, and consequently of the circulation of the blood, especially towards the head. For, in the first place, that turgescence peculiar to the brain on account of which it presses against its walls is increased by this; therefore it forces itself out of any opening in these which has been occasioned by some injury; and secondly, from the requisite strength of the heart the brain receives that internal movement different from its constant rising and sinking at every breath, which consists in a shaking of its whole mass at every pulsation of the four cerebral arteries, and the energy of which must correspond to the here increased quantity of the brain, as this movement in general is an indispensable condition of its activity. To this, therefore, small stature and especially a short neck is favourable, because by the shorter path the blood reaches the brain with more energy; and on this account great minds have seldom large bodies. Yet that shortness of the distance is not indispensable; for example, Goethe was of more than middle height. If, however, the whole condition connected with the circulation of the blood, and therefore coming from the father is wanting, the good quality of the brain coming from the mother, will at most produce a man of talent, a fine understanding, which the phlegmatic temperament thus introduced supports; but a phlegmatic genius is impossible. This condition coming from the father explains many faults of temperament described above. But, on the other hand, if this condition exists without the former, thus with an ordinarily or even badly constructed brain, it gives vivacity without mind, heat without light, hot-headed persons, men of unsupportable restlessness and petulance. That of two brothers only one has genius, and that one generally the elder, as, for example, in Kant's case, is primarily to be explained from the fact that the father was at the age of strength and passion only when he was begotten; although also the other condition originating with the mother may be spoiled by unfavourable circumstances.

I have further to add here a special remark on the childlike character of the genius, *i.e.*, on a certain resemblance which exists between genius and the age of childhood. In childhood, as in the case of genius, the cerebral and nervous system decidedly preponderates, for its development hurries far in advance of that of the rest of the organism; so that already at the seventh year the brain has attained its full extension and mass. Therefore, Bichat says: "Dans l'enfance le système nerveux, comparé au musculaire, est proportionellement plus considérable que dans tous les âges suivans, tandis

que par la suite, la pluspart des autres systèmes prédominent sur celui-ci. On sait que, pour bien voir les nerfs, on choisit toujours les enfans" (*De la vie et de la mort*, art. 8, § 6). On the other hand, the development of the genital system begins latest, and irritability, reproduction, and genital function are in full force only at the age of manhood, and then, as a rule, they predominate over the brain function. Hence it is explicable that children, in general, are so sensible, reasonable, desirous of information, and teachable, nay, on the whole, are more disposed and fitted for all theoretical occupation than grown-up people. They have, in consequence of that course of development, more intellect than will, *i.e.*, than inclinations, desire, and passion. For intellect and brain are one, and so also is the genital system one with the most vehement of all desires: therefore I have called the latter the focus of the will. Just because the fearful activity of this system still slumbers, while that of the brain has already full play, childhood is the time of innocence and happiness, the paradise of life, the lost Eden on which we look longingly back through the whole remaining course of our life. But the basis of that happiness is that in childhood our whole existence lies much more in knowing than in willing — a condition which is also supported from without by the novelty of all objects. Hence in the morning sunshine of life the world lies before us so fresh, so magically gleaming, so attractive. The small desires, the weak inclinations, and trifling cares of childhood are only a weak counterpoise to that predominance of intellectual activity. The innocent and clear glance of children, at which we revive ourselves, and which sometimes in particular cases reaches the sublime contemplative expression with which Raphael has glorified his cherubs, is to be explained from what has been said. Accordingly the mental powers develop much earlier than the needs they are destined to serve; and here, as everywhere, nature proceeds very designedly. For in this time of predominating intelligence the man collects a great store of knowledge for future wants which at the time are foreign to him. Therefore his intellect, now unceasingly active, eagerly apprehends all phenomena, broods over them and stores them up carefully for the coming time, — like the bees, who gather a great deal more honey than they can consume, in anticipation of future need. Certainly what a man acquires of insight and knowledge up to the age of puberty is, taken as a whole, more than all that he afterwards learns, however learned he may become; for it is the foundation of all human knowledge. Up till the same time plasticity predominates in the

child's body, and later, by a metastasis, its forces throw themselves into the system of generation; and thus with puberty the sexual passion appears, and now, little by little, the will gains the upper hand. Then childhood, which is prevailingly theoretical and desirous of learning, is followed by the restless, now stormy, now melancholy, period of youth, which afterwards passes into the vigorous and earnest age of manhood. Just because that impulse pregnant with evil is wanting in the child is its volition so adapted and subordinated to knowledge, whence arises that character of innocence, intelligence, and reasonableness which is peculiar to the age of childhood. On what, then, the likeness between childhood and genius depends I scarcely need to express further: upon the surplus of the powers of knowledge over the needs of the will, and the predominance of the purely intellectual activity which springs from this. Really every child is to a certain extent a genius, and the genius is to a certain extent a child. The relationship of the two shows itself primarily in the naïveté and sublime simplicity which is characteristic of true genius; and besides this it appears in several traits, so that a certain childishness certainly belongs to the character of the genius. In Riemer's "*Mittheilungen über Goethe*" (vol. i. p. 184) it is related that Herder and others found fault with Goethe, saying he was always a big child. Certainly they were right in what they said, but they were not right in finding fault with it. It has also been said of Mozart that all his life he remained a child (Nissen's Biography of Mozart, p. 2 and 529). Schlichtegroll's "*Nekrology*" (for 1791, vol. ii. p. 109) says of him: "In his art he early became a man, but in all other relations he always remained a child." Every genius is even for this reason a big child; he looks out into the world as into something strange, a play, and therefore with purely objective interest. Accordingly he has just as little as the child that dull gravity of ordinary men, who, since they are capable only of subjective interests, always see in things mere motives for their action. Whoever does not to a certain extent remain all his life a big child, but becomes a grave, sober, thoroughly composed, and reasonable man, may be a very useful and capable citizen of this world; but never a genius. In fact, the genius is so because that predominance of the sensible system and of intellectual activity which is natural to childhood maintains itself in him in an abnormal manner through his whole life, thus here becomes perennial. A trace of this certainly shows itself in many ordinary men up to the period of their youth; therefore, for example, in many students a purely intellectual tendency and

an eccentricity suggestive of genius is unmistakable. But nature returns to her track; they assume the chrysalis form and reappear at the age of manhood, as incarnate Philistines, at whom we are startled when we meet them again in later years. Upon all this that has been expounded here depends Goethe's beautiful remark: "Children do not perform what they promise; young people very seldom; and if they do keep their word, the world does not keep its word with them" (*Wahlverwandtschaften*, Pt. i. ch. 10) — the world which afterwards bestows the crowns which it holds aloft for merit on those who are the tools of its low aims or know how to deceive it. In accordance with what has been said, as there is a mere beauty of youth, which almost every one at some time possesses (beauté du diable), so there is a mere intellectuality of youth, a certain mental nature disposed and adapted for apprehending, understanding, and learning, which every one has in childhood, and some have still in youth, but which is afterwards lost, just like that beauty. Only in the case of a very few, the chosen, the one, like the other, lasts through the whole life; so that even in old age a trace of it still remains visible: these are the truly beautiful and the men of true genius.

The predominance of the cerebral nervous system and of intelligence in childhood, which is here under consideration, together with the decline of it in riper age, receives important illustration and confirmation from the fact that in the species of animals which stands nearest to man, the apes, the same relation is found in a striking degree. It has by degrees become certain that the highly intelligent orang-outang is a young pongo, which when it has grown up loses the remarkable human look of its countenance, and also its astonishing intelligence, because the lower and brutal part of its face increases in size, the forehead thereby recedes, large cristæ, muscular developments, give the skull a brutish form, the activity of the nervous system sinks, and in its place extraordinary muscular strength develops, which, as it is sufficient for its preservation, makes the great intelligence now superfluous. Especially important is what Fréd. Cuvier has said in this reference, and Flourens has illustrated in a review of the "*Histoire Naturelle*" of the former, which appeared in the September number of the "*Journal des Savans*" of 1839, and was also separately printed with some additions, under the title, "*Résumé analytique des observations de Fr. Cuvier sur l'instinct et l'intelligence des animaux*," *p. Flourens*, 1841. It is

there said, p. 50: “L’intelligence de l’orang-outang, cette intelligence si développée, et développée de si bonne heure, décroit avec l’âge. L’orang-outang, lorsqu’il est jeune, nous étonne par sa pénétration, par sa ruse, par son adresse; l’orang-outang, devenu adulte, n’est plus qu’un animal grossier, brutal, intraitable. Et il en est de tous les singes comme de l’orang-outang. Dans tous, l’intelligence décroit à mesure que les forces s’accroissent. L’animal qui a le plus d’intelligence, n’a toute cette intelligence que dans le jeune âge.” Further, p. 87: “Les singes de tous les genres offrent ce rapport inverse de l’âge et de l’intelligence. Ainsi, par exemple, l’Entelle (espèce de guenon du sous-genre des Semno-pithèques et l’un des singes vénérés dans la religion des Brames) a, dans le jeune âge, le front large, le museau peu saillant, le crâne élevé, arrondi, etc. Avec l’âge le front disparait, recule, le museau proémine; et le moral ne change pas moins que le physique: l’apathie, la violence, le besoin de solitude, remplacent la pénétration, la docilité, la confiance. *‹ Ces différences sont si grandes, ›* dit Mr. Fréd. Cuvier, *‹ que dans l’habitude où nous sommes de juger des actions des animaux par les nôtres, nous prendrions le jeune animal pour un individu de l’âge, où toutes les qualités morales de l’espèce sont acquises, et l’Entelle adulte pour un individu qui n’aurait encore que ses forces physiques. Mais la nature n’en agit pas ainsi avec ces animaux, qui ne doivent pas sortir de la sphère étroite, qui leur est fixée, et à qui il suffit en quelque sorte de pouvoir veiller à leur conservation. Pour cela l’intelligence était nécessaire, quand la force n’existait pas, et quand celle-ci est acquise, toute autre puissance perd de son utilité. ›*” And p. 118: “La conservation des espèces ne repose pas moins sur les qualités intellectuelles des animaux, que sur leurs qualités organiques.” This last confirms my principle that the intellect, like the claws and teeth, is nothing else than a weapon in the service of the will.

Chapter XXXII.[14] On Madness.

The health of the mind properly consists in perfect recollection. Of course this is not to be understood as meaning that our memory preserves everything. For the past course of our life shrinks up in time, as the path of the wanderer looking back shrinks up in space: sometimes it is difficult for us to distinguish the particular years; the days have for the most part become unrecognisable. Really, however, only the exactly similar events, recurring an innumerable number of times, so that their images, as it were, conceal each other, ought so to run together in the memory that they are individually unrecognisable; on the other hand, every event in any way peculiar or significant we must be able to find again in memory, if the intellect is normal, vigorous, and quite healthy. In the text I have explained madness as the broken thread of this memory, which still runs on regularly, although in constantly decreasing fulness and distinctness. The following considerations may serve to confirm this.

The memory of a healthy man affords a certainty as to an event he has witnessed, which is regarded as just as firm and sure as his present apprehension of things; therefore, if sworn to by him, this event is thereby established in a court of law. On the other hand, the mere suspicion of madness will at once weaken the testimony of a witness. Here, then, lies the criterion between the healthy mind and insanity. Whenever I doubt whether an event which I remember really took place, I throw upon myself the suspicion of madness: unless it is that I am uncertain whether it was not a mere dream. If another doubts the reality of an event, related by me as an eye-witness, without mistrusting my honesty, then he regards me as insane. Whoever comes at last, through constantly recounting an event which originally was fabricated by him, to believe in it himself is, in this one point, really insane. We may ascribe to an insane person flashes of wit, single clever thoughts, even correct judgments, but his testimony as to past events no man will consider valid. In the Lalita-vistara, well known to be the history of Buddha Sakya-Muni, it is related that at the moment of his birth all the sick became well, all the blind saw, all the deaf heard, and all mad people "recovered their memory." This last is mentioned in two passages.[15]

My own experience of many years has led me to the opinion that madness occurs proportionally most frequently among actors. But what a misuse they make of their memory! Daily they have to learn a new part or refresh an old one; but these parts are entirely without connection, nay, are in contradiction and contrast with each other, and every evening the actor strives to forget himself entirely and be some quite different person. This kind of thing paves the way for madness.

The exposition of the origin of madness given in the text will become more comprehensible if it is remembered how unwillingly we think of things which powerfully injure our interests, wound our pride, or interfere with our wishes; with what difficulty do we determine to lay such things before our own intellect for careful and serious investigation; how easily, on the other hand, we unconsciously break away or sneak off from them again; how, on the contrary, agreeable events come into our minds of their own accord, and, if driven away, constantly creep in again, so that we dwell on them for hours together. In that resistance of the will to allowing what is contrary to it to come under the examination of the intellect lies the place at which madness can break in upon the mind. Each new adverse event must be assimilated by the intellect, *i.e.*, it must receive a place in the system of the truths connected with our will and its interests, whatever it may have to displace that is more satisfactory. Whenever this has taken place, it already pains us much less; but this operation itself is often very painful, and also, in general, only takes place slowly and with resistance. However, the health of the mind can only continue so long as this is in each case properly carried out. If, on the contrary, in some particular case, the resistance and struggles of the will against the apprehension of some knowledge reaches such a degree that that operation is not performed in its integrity, then certain events or circumstances become for the intellect completely suppressed, because the will cannot endure the sight of them, and then, for the sake of the necessary connection, the gaps that thus arise are filled up at pleasure; thus madness appears. For the intellect has given up its nature to please the will: the man now imagines what does not exist. Yet the madness which has thus arisen is now the lethe of unendurable suffering; it was the last remedy of harassed nature, *i.e.*, of the will.

Let me mention here in passing a proof of my view which is worth noticing. Carlo Gozzi, in the "*Monstro turchino*," act i. scene 2, presents to

us a person who has drunk a magic potion which produces forgetfulness, and this person appears exactly like a madman.

In accordance with the above exposition one may thus regard the origin of madness as a violent "casting out of the mind" of anything, which, however, is only possible by "taking into the head" something else. The converse process is more rare, that the "taking into the head" comes first, and the "casting out of the mind" second. It takes place, however, in those cases in which the occasion of insanity is kept constantly present to the mind and cannot be escaped from; thus, for example, in the case of many who have gone mad from love, erotomaniacs, where the occasion of their madness is constantly longed after; also in the case of madness which has resulted from the fright of some sudden horrible occurrence. Such patients cling, as it were, convulsively to the thought they have grasped, so that no other, or at least none opposed to it, can arise. In both processes, however, what is essential to madness remains the same, the impossibility of a uniformly connected recollection, such as is the basis of our healthy and rational reflection. Perhaps the contrast of the ways in which they arise, set forth here, might, if applied with judgment, afford a sharp and profound principle of division of delusions proper.

For the rest, I have only considered the physical origin of madness, thus what is introduced by external, objective occasions. More frequently, however, it depends upon purely physical causes, upon malformations or partial disorganisation of the brain or its membranes, also upon the influence which other parts affected with disease exercise upon the brain. Principally in the latter kind of madness false sense-perceptions, hallucinations, may arise. Yet the two causes of madness will generally partake of each other, particularly the psychical of the physical. It is the same as with suicide, which is rarely brought about by an external occasion alone, but a certain physical discomfort lies at its foundation; and according to the degree which this attains to a greater or less external occasion is required; only in the case of the very highest degree is no external occasion at all required. Therefore there is no misfortune so great that it would influence every one to suicide, and none so small that one like it has not already led to it. I have shown the psychical origin of madness as, at least according to all appearance, it is brought about in the healthy mind by a great misfortune. In the case of those who are already strongly disposed to madness physically a very small disappointment will be sufficient to induce

it. For example, I remember a man in a madhouse who had been a soldier, and had gone out of his mind because his officer had addressed him as Er.[16] In the case of decided physical disposition no occasion at all is required when this has come to maturity. The madness which has sprung from purely psychical causes may, perhaps, by the violent perversion of the course of thought which has produced it, also introduce a kind of paralysis or other depravity of some part of the brain, which, if not soon done away with, becomes permanent. Therefore madness is only curable at first, and not after a longer time.

Pinel taught that there is a mania sine delirio, frenzy without insanity. This was controverted by Esquirol, and since then much has been said for and against it. The question can only be decided empirically. But if such a state really does occur, then it is to be explained from the fact that here the will periodically entirely withdraws itself from the government and guidance of the intellect, and consequently of motives, and thus it then appears as a blind, impetuous, destructive force of nature, and accordingly manifests itself as the desire to annihilate everything that comes in its way. The will thus let loose is like the stream which has broken through the dam, the horse that has thrown his rider, or a clock out of which the regulating screws have been taken. Yet only the reason, thus reflective knowledge, is included in that suspension, not intuitive knowledge also; otherwise the will would remain entirely without guidance, and consequently the man would be immovable. But, on the contrary, the man in a frenzy apprehends objects, for he breaks out upon them; thus he has also consciousness of his present action, and afterwards remembrance of it. But he is entirely without reflection, thus without any guidance of the reason, consequently quite incapable of any consideration or regard for the present, the past, or the future. When the attack is over, and the reason has regained its command, its function is correct, because here its proper activity has not been perverted or destroyed, but only the will has found the means to withdraw itself from it entirely for a while.

Chapter XXXIII.[17] Isolated Remarks On Natural Beauty.

What contributes among other things to make the sight of a beautiful landscape so exceedingly delightful is the perfect truth and consistency of nature. Certainly nature does not follow here the guidance of logic in the connection of the grounds of knowledge, of antecedents and consequences, premisses and conclusions; but still it follows what is for it analogous to the law of causality in the visible connection of causes and effects. Every modification, even the slightest, which an object receives from its position, foreshortening, concealment, distance, lighting, linear and atmospheric perspective, &c., is, through its effect upon the eye, unerringly given and accurately taken account of: the Indian proverb, “Every corn of rice casts its shadow,” finds here its confirmation. Therefore here everything shows itself so consistent, accurately regular, connected, and scrupulously right; here there are no evasions. If now we consider the sight of a beautiful view, merely as a brain-phenomenon, it is the only one among the complicated brain-phenomena which is always absolutely regular, blameless, and perfect; all the rest, especially our own mental operations, are, in form or material, affected more or less with defects or inaccuracies. From this excellence of the sight of beautiful nature, is the harmonious and thoroughly satisfying character of its impression to be explained, and also the favourable effect which it has upon our whole thought, which in its formal part thereby becomes more correctly disposed, and to a certain extent purified, for that brain-phenomenon which alone is entirely faultless sets the brain in general in perfectly normal action; and now the thought seeks to follow that method of nature in the consistency, connectedness, regularity, and harmony of all its processes, after being brought by it into the right swing. A beautiful view is therefore a cathartic of the mind, as music, according to Aristotle, is of the feeling, and in its presence one will think most correctly.

That the sight of a mountain chain suddenly rising before us throws us so easily into a serious, and even sublime mood may partly depend upon the fact that the form of the mountains and the outline of the chain arising from it is the only constantly permanent line of the landscape, for the mountains alone defy the decay which soon sweeps away everything else, especially our own ephemeral person. Not that at the sight of the mountain chain all

this appeared distinctly in our consciousness, but an obscure feeling of it is the fundamental note of our mood.

I would like to know why it is that while for the human form and countenance light from above is altogether the most advantageous, and light from below the most unfavourable, with regard to landscape nature exactly the converse holds good.

Yet how æsthetic is nature! Every spot that is entirely uncultivated and wild, *i.e.*, left free to itself, however small it may be, if only the hand of man remains absent, it decorates at once in the most tasteful manner, clothes it with plants, flowers, and shrubs, whose unforced nature, natural grace, and tasteful grouping bears witness that they have not grown up under the rod of correction of the great egoist, but that nature has here moved freely. Every neglected plant at once becomes beautiful. Upon this rests the principle of the English garden, which is as much as possible to conceal art, so that it may appear as if nature had here moved freely; for only then is it perfectly beautiful, *i.e.*, shows in the greatest distinctness the objectification of the still unconscious will to live, which here unfolds itself with the greatest naïveté, because the forms are not, as in the animal world, determined by external ends, but only immediately by the soil, climate, and a mysterious third influence on account of which so many plants which have originally sprung up in the same soil and climate yet show such different forms and characters.

The great difference between the English, or more correctly the Chinese, garden and the old French, which is now always becoming more rare, yet still exists in a few magnificent examples, ultimately rests upon the fact that the former is planned in an objective spirit, the latter in a subjective. In the former the will of nature, as it objectifies itself in tree and shrub, mountain and waterfall, is brought to the purest possible expression of these its Ideas, thus of its own inner being. In the French garden, on the other hand, only the will of the possessor of it is mirrored, which has subdued nature so that instead of its Ideas it bears as tokens of its slavery the forms which correspond to that will, and which are forcibly imposed upon it — clipped hedges, trees cut into all kinds of forms, straight alleys, arched avenues, &c.

Chapter XXXIV.[18] On The Inner Nature Of Art.

Not merely philosophy but also the fine arts work at bottom towards the solution of the problem of existence. For in every mind that once gives itself up to the purely objective contemplation of nature a desire has been excited, however concealed and unconscious it may be, to comprehend the true nature of things, of life and existence. For this alone has interest for the intellect as such, *i.e.*, for the pure subject of knowledge which has become free from the aims of the will; as for the subject which knows as a mere individual the aims of the will alone have interest. On this account the result of the purely objective apprehension of things is an expression more of the nature of life and existence, more an answer to the question, "What is life?" Every genuine and successful work of art answers this question in its own way with perfect correctness. But all the arts speak only the naive and childish language of perception, not the abstract and serious language of reflection; their answer is therefore a fleeting image: not permanent and general knowledge. Thus for perception every work of art answers that question, every painting, every statue, every poem, every scene upon the stage: music also answers it; and indeed more profoundly than all the rest, for in its language, which is understood with absolute directness, but which is yet untranslatable into that of the reason, the inner nature of all life and existence expresses itself. Thus all the other arts hold up to the questioner a perceptible image, and say, "Look here, this is life." Their answer, however correct it may be, will yet always afford merely a temporary, not a complete and final, satisfaction. For they always give merely a fragment, an example instead of the rule, not the whole, which can only be given in the universality of the conception. For this, therefore, thus for reflection and in the abstract, to give an answer which just on that account shall be permanent and suffice for always, is the task of philosophy. However, we see here upon what the relationship of philosophy to the fine arts rests, and can conclude from that to what extent the capacity of both, although in its direction and in secondary matters very different, is yet in its root the same.

Every work of art accordingly really aims at showing us life and things as they are in truth, but cannot be directly discerned by every one through the mist of objective and subjective contingencies. Art takes away this mist.

The works of the poets, sculptors, and representative artists in general contain an unacknowledged treasure of profound wisdom; just because out of them the wisdom of the nature of things itself speaks, whose utterances they merely interpret by illustrations and purer repetitions. On this account, however, every one who reads the poem or looks at the picture must certainly contribute out of his own means to bring that wisdom to light; accordingly he comprehends only so much of it as his capacity and culture admit of; as in the deep sea each sailor only lets down the lead as far as the length of the line will allow. Before a picture, as before a prince, every one must stand, waiting to see whether and what it will speak to him; and, as in the case of a prince, so here he must not himself address it, for then he would only hear himself. It follows from all this that in the works of the representative arts all truth is certainly contained, yet only virtualiter or implicite; philosophy, on the other hand, endeavours to supply the same truth actualiter and explicite, and therefore, in this sense, is related to art as wine to grapes. What it promises to supply would be, as it were, an already realised and clear gain, a firm and abiding possession; while that which proceeds from the achievements and works of art is one which has constantly to be reproduced anew. Therefore, however, it makes demands, not only upon those who produce its works, but also upon those who are to enjoy them which are discouraging and hard to comply with. Therefore its public remains small, while that of art is large.

The co-operation of the beholder, which is referred to above, as demanded for the enjoyment of a work of art, depends partly upon the fact that every work of art can only produce its effect through the medium of the fancy; therefore it must excite this, and can never allow it to be left out of the play and remain inactive. This is a condition of the æsthetic effect, and therefore a fundamental law of all fine arts. But it follows from this that, through the work of art, everything must not be directly given to the senses, but rather only so much as is demanded to lead the fancy on to the right path; something, and indeed the ultimate thing, must always be left over for the fancy to do. Even the author must always leave something over for the reader to think; for Voltaire has very rightly said, "Le secret d'être ennuyeux, c'est de tout dire." But besides this, in art the best of all is too spiritual to be given directly to the senses; it must be born in the imagination of the beholder, although begotten by the work of art. It depends upon this that the sketches of great masters often effect more than

their finished pictures; although another advantage certainly contributes to this, namely, that they are completed offhand in the moment of conception; while the perfected painting is only produced through continued effort, by means of skilful deliberation and persistent intention, for the inspiration cannot last till it is completed. From the fundamental æsthetical law we are speaking of, it is further to be explained why wax figures never produce an æsthetic effect, and therefore are not properly works of fine art, although it is just in them that the imitation of nature is able to reach its highest grade. For they leave nothing for the imagination to do. Sculpture gives merely the form without the colour; painting gives the colour, but the mere appearance of the form; thus both appeal to the imagination of the beholder. The wax figure, on the other hand, gives all, form and colour at once; whence arises the appearance of reality, and the imagination is left out of account. Poetry, on the contrary, appeals indeed to the imagination alone, which it sets in action by means of mere words.

An arbitrary playing with the means of art without a proper knowledge of the end is, in every art, the fundamental characteristic of the dabbler. Such a man shows himself in the pillars that support nothing, aimless volutes, juttings and projections of bad architecture, in the meaningless runs and figures, together with the aimless noise of bad music, in the jingling of the rhymes of senseless poetry, &c.

It follows from the preceding chapter, and from my whole view of art, that its aim is the facilitating of the knowledge of the Ideas of the world (in the Platonic sense, the only one which I recognise for the word Idea). The Ideas, however, are essentially something perceptible, which, therefore, in its fuller determinations, is inexhaustible. The communication of such an Idea can therefore only take place on the path of perception, which is that of art. Whoever, therefore, is filled with the comprehension of an Idea is justified if he chooses art as the medium of its communication. The mere conception, on the other hand, is something completely determinable, therefore exhaustible, and distinctly thought, the whole content of which can be coldly and dryly expressed in words. Now to desire to communicate such a conception by means of a work of art is a very useless circumlocution, indeed belongs to that playing with the means of art without knowledge of its end which has just been condemned. Therefore a work of art which has proceeded from mere distinct conceptions is always ungenuine. If now, in considering a work of plastic art, or in reading a

poem, or in hearing a piece of music (which aims at describing something definite), we see, through all the rich materials of art, the distinct, limited, cold, dry conception shine out, and at last come to the front, the conception which was the kernel of this work, the whole notion of which consequently consisted in the distinct thinking of it, and accordingly is absolutely exhausted by its communication, we feel disgusted and indignant, for we see ourselves deceived and cheated out of our interest and attention. We are only perfectly satisfied by the impression of a work of art when it leaves something which, with all our thinking about it, we cannot bring down to the distinctness of a conception. The mark of that hybrid origin from mere conceptions is that the author of a work of art could, before he set about it, give in distinct words what he intended to present; for then it would have been possible to attain his whole end through these words. Therefore it is an undertaking as unworthy as it is absurd if, as has often been tried at the present day, one seeks to reduce a poem of Shakspeare's or Goethe's to the abstract truth which it was its aim to communicate. Certainly the artist ought to think in the arranging of his work; but only that thought which was perceived before it was thought has afterwards, in its communication, the power of animating or rousing, and thereby becomes imperishable. We shall not refrain from observing here that certainly the work which is done at a stroke, like the sketches of painters already referred to, the work which is completed in the inspiration of its first conception, and as it were unconsciously dashed off, like the melody which comes entirely without reflection, and quite as if by inspiration, and finally, also the lyrical poem proper, the mere song, in which the deeply felt mood of the present, and the impression of the surroundings, as if involuntarily, pours itself forth in words, whose metre and rhyme come about of their own accord — that all these, I say, have the great advantage of being purely the work of the ecstasy of the moment, the inspiration, the free movement of genius, without any admixture of intention and reflection; hence they are through and through delightful and enjoyable, without shell and kernel, and their effect is much more inevitable than that of the greatest works of art, of slower and more deliberate execution. In all the latter, thus in great historical paintings, in long epic poems, great operas, &c., reflection, intention, and deliberate selection has had an important part; understanding, technical skill, and routine must here fill up the gaps which the conception and inspiration of genius has left, and must mix with these all kinds of

necessary supplementary work as cement of the only really genuinely brilliant parts. This explains why all such works, only excepting the perfect masterpieces of the very greatest masters (as, for example, “Hamlet,” “Faust,” the opera of “Don Juan”), inevitably contain an admixture of something insipid and wearisome, which in some measure hinders the enjoyment of them. Proofs of this are the “Messiah,” “*Gerusalemme liberata*,” even “Paradise Lost” and the “Æneid;” and Horace already makes the bold remark, “Quandoque dormitat bonus Homerus.” But that this is the case is the consequence of the limitation of human powers in general.

The mother of the useful arts is necessity; that of the fine arts superfluity. As their father, the former have understanding; the latter genius, which is itself a kind of superfluity, that of the powers of knowledge beyond the measure which is required for the service of the will.

Chapter XXXV.[19] On The Æsthetics Of Architecture.

In accordance with the deduction given in the text of the pure æsthetics of architecture from the lowest grades of the objectification of the will or of nature, the Ideas of which it seeks to bring to distinct perception, its one constant theme is support and burden, and its fundamental law is that no burden shall be without sufficient support, and no support without a suitable burden; consequently that the relation of these two shall be exactly the fitting one. The purest example of the carrying out of this theme is the column and entablature. Therefore the order or columnar arrangement has become, as it were, the thorough bass of the whole of architecture. In column and entablature the support and the burden are completely separated; whereby the reciprocal action of the two and their relation to each other becomes apparent. For certainly even every plain wall contains support and burden; but here the two are still fused together. All is here support and all is burden; hence there is no æsthetic effect. This first appears through the separation, and takes place in proportion to its degree. For between the row of columns and the plain wall there are many intermediate degrees. Even in the mere breaking up of the wall of a house by windows and doors one seeks at least to indicate that separation by flat projecting pilasters (antæ) with capitals, which are inserted under the mouldings, nay, in case of need, are represented by mere painting, in order to indicate in some way the entablature and an order. Real pillars, and also consoles and supports of various kinds, realise more that pure separation of support and burden which is striven after throughout by architecture. In this respect, next to the column with the entablature, but as a special construction not imitating it, stands the vault with the pillar. The latter certainly is far from attaining to the æsthetic effect of the former, because here the support and the burden are not purely separated, but are fused, passing over into each other. In the vault itself every stone is at once burden and support, and even the pillars, especially in groined vaulting, are, at least apparently, held in position by the pressure of opposite arches; and also just on account of this lateral pressure not only vaults but even mere arches ought not to rest upon columns, but require the massive four-cornered pillars. In the row of columns alone is the separation complete, for here the entablature appears as pure burden, the column as pure support.

Accordingly the relation of the colonnade to the plain wall may be compared to that which would exist between a scale ascending in regular intervals and a tone ascending little by little from the same depth to the same height without gradation, which would produce a mere howl. For in the one as in the other the material is the same, and the important difference proceeds entirely from the pure separation.

Moreover, the support is not adapted to the burden when it is only sufficient to bear it, but when it can do this so conveniently and amply that at the first glance we are quite at ease about it. Yet this superfluity of support must not exceed a certain degree; for otherwise we will perceive support without burden, which is opposed to the æsthetic end. As a rule for determining that degree the ancients devised the line of equilibrium, which is got by carrying out the diminution of the thickness of the column as it ascends till it runs out into an acute angle, whereby the column becomes a cone; now every cross section will leave the lower part so strong that it is sufficient to support the upper part cut off. Commonly, however, one builds with twentyfold strength, *i.e.*, one lays upon every support only 1/20th of the maximum it could bear. A glaring example of burden without support is presented to the eye by the balconies at the corners of many houses built in the elegant style of the present day. We do not see what supports them; they seem to hang suspended, and disturb the mind.

That in Italy even the simplest and most unornamented buildings make an æsthetic impression, while in Germany this is not the case, depends principally upon the fact that in Italy the roofs are very flat. A high roof is neither support nor burden, for its two halves mutually support each other, but the whole has no weight corresponding to its extension. Therefore it presents to the eye an extended mass which is entirely foreign to the æsthetic end, serves merely a useful end, consequently disturbs the former, of which the theme is always only support and burden.

The form of the column has its sole ground in the fact that it affords the simplest and most suitable support. In the twisted column inappropriateness appears as if with intentional perversity, and therefore shamelessness: hence good taste condemns it at the first glance. The four-cornered pillar, since the diagonal exceeds the sides, has unequal dimensions of thickness which have no end as their motive, but are occasioned by the accident of greater feasibleness; and just on this account it pleases us so very much less than the column. Even the hexagonal or octagonal pillar is more pleasing,

because it approaches more nearly to the round column; for the form of the latter alone is exclusively determined by the end. It is, however, also so determined in all its other proportions, primarily in the relation of its thickness to its height, within the limits permitted by the difference of the three columnar orders. Therefore its diminution from the first third of its height upwards, and also a slight increase of its thickness just at this place (entasis vitr.), depends upon the fact that the pressure of the burden is greatest there. It has hitherto been believed that this increase in thickness was peculiar to the Ionic and Corinthian columns alone, but recent measurements have shown it also in the Doric columns, even at Pæstum. Thus everything in the column, its thoroughly determined form, the proportion of its height to its thickness, of both to the intervals between the columns, and that of the whole series to the entablature and the burden resting upon it, is the exactly calculated result of the relation of the necessary support to the given burden. As the latter is uniformly distributed, so must also the support be; therefore groups of columns are tasteless. On the other hand, in the best Doric temples the corner column comes somewhat nearer to the next ones, because the meeting of the entablatures at the corner increases the burden; and in this the principle of architecture expresses itself distinctly, that the structural relations, *i.e.*, the relations between support and burden, are the essential ones, to which the relations of symmetry, as subordinate, must at once give way. According to the weight of the whole burden generally will the Doric or the two lighter orders of columns be chosen, for the first, not only by the greater thickness, but also by the closer position of the columns, which is essential to it, is calculated for heavier burdens, to which end also the almost crude simplicity of its capital is suited. The capitals in general serve the end of showing visibly that the columns bear the entablature, and are not stuck in like pins; at the same time they increase by means of their abacus the bearing surface. Since, then, all the laws of columnar arrangement, and consequently also the form and proportion of the column, in all its parts and dimensions down to the smallest details, follow from the thoroughly understood and consistently carried out conception of the amply adequate support of a given burden, thus so far are determined a priori, it comes out clearly how perverse is the thought, so often repeated, that the stems of trees, or even (which unfortunately even “Vitruvius,” iv. 1, expresses) the human form has been the prototype of the column. For if the form of the column were for

architecture a purely accidental one, taken from without, it could never appeal to us so harmoniously and satisfactorily whenever we behold it in its proper symmetry; nor, on the other hand, could every even slight disproportion of it be felt at once by the fine and cultivated sense as disagreeable and disturbing, like a false note in music. This is rather only possible because, according to the given end and means, all the rest is essentially determined a priori, as in music, according to the given melody and key, the whole harmony is essentially so determined. And, like music, architecture in general is also not an imitative art, although both are often falsely taken to be so.

Æsthetic satisfaction, as was fully explained in the text, always depends upon the apprehension of a (Platonic) Idea. For architecture, considered merely as a fine art, the Ideas of the lowest grades of nature, such as gravity, rigidity, and cohesion, are the peculiar theme; but not, as has hitherto been assumed, merely regular form, proportion, and symmetry, which, as something purely geometrical, properties of space, are not Ideas, and therefore cannot be the theme of a fine art. Thus in architecture also they are of secondary origin, and have a subordinate significance, which I shall bring out immediately. If it were the task of architecture as a fine art simply to exhibit these, then the model would have the same effect as the finished work. But this is distinctly not the case; on the contrary, the works of architecture, in order to act æsthetically, absolutely must have a considerable size; nay, they can never be too large, but may easily be too small. Indeed ceteris paribus the æsthetic effect is in exact proportion to the size of the building, because only great masses make the action of gravitation apparent and impressive in a high degree. But this confirms my view that the tendency and antagonism of those fundamental forces of nature constitute the special æsthetical material of architecture, which, according to its nature, requires large masses in order to become visible, and indeed capable of being felt. The forms in architecture, as was shown above in the case of the column, are primarily determined by the immediate structural end of each part. But so far as this leaves anything undetermined, the law of the most perfect clearness to perception, thus also of the easiest comprehensibility, comes in; for architecture has its existence primarily in our spatial perception, and accordingly appeals to our a priori faculty for this. But these qualities always result from the greatest regularity of the forms and rationality of their relations. Therefore beautiful architecture

selects only regular figures composed of straight lines or regular curves, and also the bodies which result from these, such as cubes, parallelopipeda, cylinders, spheres, pyramids, and cones; but as openings sometimes circles or ellipses, yet, as a rule, quadrates, and still oftener rectangles, the latter of thoroughly rational and very easily comprehended relation of their sides (not, for instance as 6:7, but as 1:2, 2:3), finally also blind windows or niches of regular and comprehensible proportions. For the same reason it will readily give to the buildings themselves and their large parts a rational and easily comprehended relation of height and breadth; for example, it will let the height of a facade be half the breadth, and place the pillars so that every three or four of them, with the intervals between them, will measure a line which is equal to the height, thus will form a quadrate. The same principle of perceptibility and easy comprehension demands also that a building should be easily surveyed. This introduces symmetry, which is further necessary to mark out the work as a whole, and to distinguish its essential from its accidental limitation; for sometimes, for example, it is only under the guidance of symmetry that one knows whether one has before one three buildings standing beside each other or only one. Thus only by means of symmetry does a work of architecture at once announce itself as individual unity, and as the development of a central thought.

Now although, as was cursorily shown above, architecture has by no means to imitate the forms of nature, such as the stems of trees or even the human figure, yet it ought to work in the spirit of nature, for it makes the law its own, natura nihil agit frustra, nihilque supervacaneum, et quod commodissimum in omnibus suis operationibus sequitur, and accordingly avoids everything which is even only apparently aimless, and always attains the end in view in each case, whether this is purely architectonic, *i.e.*, structural, or an end connected with usefulness, by the shortest and most natural path, and thus openly exhibits the end through the work itself. Thus it attains a certain grace, analogous to that which in living creatures consists in the ease and suitableness of every movement and position to its end. Accordingly we see in the good antique style of architecture every part, whether pillar, column, arch, entablature, or door, window, stair, or balcony, attain its end in the directest and simplest manner, at the same time displaying it openly and naively; just as organised nature also does in its works. The tasteless style of architecture, on the contrary, seeks in everything useless roundabout ways, and delights in caprices, thereby hits

upon aimlessly broken and irregular entablatures, grouped columns, fragmentary cornices on door arches and gables, meaningless volutes, scrolls, and such like. It plays with the means of the art without understanding its aims, as children play with the tools of grown-up people. This was given above as the character of the bungler. Of this kind is every interruption of a straight line, every alteration in the sweep of a curve, without apparent end. On the other hand, it is also just that naive simplicity in the disclosure and attainment of the end, corresponding to the spirit in which nature works and fashions, that imparts such beauty and grace of form to antique pottery that it ever anew excites our wonder, because it contrasts so advantageously in original taste with our modern pottery, which bears the stamp of vulgarity, whether it is made of porcelain or common potter's clay. At the sight of the pottery and implements of the ancients we feel that if nature had wished to produce such things it would have done so in these forms. Since, then, we see that the beauty of architecture arises from the unconcealed exhibition of the ends, and the attainment of them by the shortest and most natural path, my theory here appears in direct contradiction with that of Kant, which places the nature of all beauty in an apparent design without an end.

The sole theme of architecture here set forth — support and burden — is so very simple, that just on this account this art, so far as it is a fine art (but not so far as it serves useful ends), is perfect and complete in essential matters, since the best Greek period, at least, is not susceptible of any important enrichment. On the other hand, the modern architect cannot noticeably depart from the rules and patterns of the ancients without already being on the path of deterioration. Therefore there remains nothing for him to do but to apply the art transmitted to him by the ancients, and carry out the rules so far as is possible under the limitations which are inevitably laid down for him by wants, climate, age, and country. For in this art, as in sculpture, the effort after the ideal unites with the imitation of the ancients.

I scarcely need to remind the reader that in all these considerations I have had in view antique architecture alone, and not the so-called Gothic style, which is of Saracen origin, and was introduced by the Goths in Spain to the rest of Europe. Perhaps a certain beauty of its own kind is not altogether to be denied to this style, but yet if it attempts to oppose itself to the former as its equal, then this is a barbarous presumption which must not be allowed for a moment. How beneficently, after contemplating such

Gothic magnificence, does the sight of a building correctly carried out in the antique style act upon our mind! We feel at once that this alone is right and true. If one could bring an ancient Greek before our most celebrated Gothic cathedrals, what would he say to them? — Βαρβαροι! Our pleasure in Gothic works certainly depends for the most part upon the association of ideas and historical reminiscences, thus upon a feeling which is foreign to art. All that I have said of the true æsthetic end, of the spirit and the theme of architecture, loses in the case of these works its validity. For the freely lying entablature has vanished, and with it the columns: support and burden, arranged and distributed in order to give visible form to the conflict between rigidity and gravity, are here no longer the theme. Moreover, that thorough, pure rationality by virtue of which everything admits of strict account, nay, already presents it of its own accord to the thoughtful beholder, and which belongs to the character of antique architecture, can here no longer be found; we soon become conscious that here, instead of it, a will guided by other conceptions has moved; therefore much remains unexplained to us. For only the antique style of architecture is conceived in a purely objective spirit; the Gothic style is more in the subjective spirit. Yet as we have recognised the peculiar æsthetic fundamental thought of antique architecture in the unfolding of the conflict between rigidity and gravity, if we wish to discover in Gothic architecture also an analogous fundamental thought, it will be this, that here the entire overcoming and conquest of gravity by rigidity is supposed to be exhibited. For in accordance with this the horizontal line which is that of burden has entirely vanished, and the action of gravity only appears indirectly, disguised in arches and vaults, while the vertical line which is that of support, alone prevails, and makes palpable to the senses the victorious action of rigidity, in excessively high buttresses, towers, turrets, and pinnacles without number which rise unencumbered on high. While in antique architecture the tendency and pressure from above downwards is just as well represented and exhibited as that from below upwards, here the latter decidedly predominates; whence that analogy often observed with the crystal, whose crystallisation also takes place with the overcoming of gravity. If now we attribute this spirit and fundamental thought to Gothic architecture, and would like thereby to set it up as the equally justified antithesis of antique architecture, we must remember that the conflict between rigidity and gravity, which the antique architecture so openly and naïvely expresses, is an actual and true conflict

founded in nature; the entire overcoming of gravity by rigidity, on the contrary, remains a mere appearance, a fiction accredited by illusion. Every one will easily be able to see clearly how from the fundamental thought given here, and the peculiarities of Gothic architecture noticed above, there arises that mysterious and hyperphysical character which is attributed to it. It principally arises, as was already mentioned, from the fact that here the arbitrary has taken the place of the purely rational, which makes itself known as the thorough adaptation of the means to the end. The many things that are really aimless, but yet are so carefully perfected, raise the assumption of unknown, unfathomed, and secret ends, *i.e.*, give the appearance of mystery. On the other hand, the brilliant side of Gothic churches is the interior; because here the effect of the groined vaulting borne by slender, crystalline, aspiring pillars, raised high aloft, and, all burden having disappeared, promising eternal security, impresses the mind; while most of the faults which have been mentioned lie upon the outside. In antique buildings the external side is the most advantageous, because there we see better the support and the burden; in the interior, on the other hand, the flat roof always retains something depressing and prosaic. For the most part, also, in the temples of the ancients, while the outworks were many and great, the interior proper was small. An appearance of sublimity is gained from the hemispherical vault of a cupola, as in the Pantheon, of which, therefore, the Italians also, building in this style, have made a most extensive use. What determines this is, that the ancients, as southern peoples, lived more in the open air than the northern nations who have produced the Gothic style of architecture. Whoever, then, absolutely insists upon Gothic architecture being accepted as an essential and authorised style may, if he is also fond of analogies, regard it as the negative pole of architecture, or, again, as its minor key. In the interest of good taste I must wish that great wealth will be devoted to that which is objectively, *i.e.*, actually, good and right, to what in itself is beautiful, but not to that whose value depends merely upon the association of ideas. Now when I see how this unbelieving age so diligently finishes the Gothic churches left incomplete by the believing Middle Ages, it looks to me as if it were desired to embalm a dead Christianity.

Chapter XXXVI.[20] Isolated Remarks On The Æsthetics Of The Plastic And Pictorial Arts.

In sculpture beauty and grace are the principal things; but in painting expression, passion, and character predominate; therefore just so much of the claims of beauty must be neglected. For a perfect beauty of all forms, such as sculpture demands, would detract from the characteristic and weary by monotony. Accordingly painting may also present ugly faces and emaciated figures; sculpture, on the other hand, demands beauty, although not always perfect, but, throughout, strength and fulness of the figures. Consequently a thin Christ upon the Cross, a dying St. Jerome, wasted by age and disease, like the masterpiece of Domenichino, is a proper subject for painting; while, on the contrary, the marble figure by Donatello, in the gallery at Florence, of John the Baptist, reduced to skin and bone by fasting, has, in spite of the masterly execution, a repulsive effect. From this point of view sculpture seems suitable for the affirmation, painting for the negation, of the will to live, and from this it may be explained why sculpture was the art of the ancients, while painting has been the art of the Christian era.

In connection with the exposition given in § 45 of the first volume, that the discovery, recognition, and retention of the type of human beauty depends to a certain extent upon an anticipation of it, and therefore in part has an a priori foundation, I find that I have yet to bring out clearly the fact that this anticipation nevertheless requires experience, by which it may be stirred up; analogous to the instinct of the brutes, which, although guiding the action a priori, yet requires determination by motives in the details of it. Experience and reality present to the intellect of the artist human forms, which, in one part or another, are more or less true to nature, as if it were asking for his judgment concerning them, and thus, after the Socratic method, call forth from that obscure anticipation the distinct and definite knowledge of the ideal. Therefore it assisted the Greek sculptors very much that the climate and customs of their country gave them opportunity the whole day of seeing half-naked forms, and in the gymnasium entirely naked forms. In this way every limb presented its plastic significance to criticism, and to comparison with the ideal which lay undeveloped in their consciousness. Thus they constantly exercised their judgment with regard to all forms and limbs, down to their finest shades of difference; and thus, little

by little, their originally dull anticipation of the ideal of human beauty was raised to such distinct consciousness that they became capable of objectifying it in works of art. In an entirely analogous manner some experience is useful and necessary to the poet for the representation of characters. For although he does not work according to experience and empirical data, but in accordance with the clear consciousness of the nature of humanity, as he finds it within himself, yet experience serves this consciousness as a pattern, incites it and gives it practice. Accordingly his knowledge of human nature and its varieties, although in the main it proceeds a priori and by anticipation, yet first receives life, definiteness, and compass through experience. But, supporting ourselves upon the preceding book and chapter 44 in the following book, we can go still deeper into the ground of that marvellous sense of beauty of the Greeks which made them alone of all nations upon earth capable of discovering the true normal type of the human form, and accordingly of setting up the pattern of beauty and grace for the imitation of all ages, and we can say: The same thing which, if it remains unseparated from the will, gives sexual instinct with its discriminating selection, *i.e.*, sexual love (which it is well known was subject among the Greeks to great aberrations), becomes, if, by the presence of an abnormally preponderating intellect, it separates itself from the will and yet remains active, the objective sense of beauty of the human form, which now shows itself primarily as a critical artistic sense, but can rise to the discovery and representation of the norm of all parts and proportions; as was the case in Phidias, Praxiteles, Scopas, &c. Then is fulfilled what Goethe makes the artist say —

“That I with mind divine
And human hand
May be able to form
What with my wife,
As animal, I can and must.”

And again, analogous to this, that which in the poet, if it remained unseparated from the will, would give only worldly prudence, becomes, if it frees itself from the will by abnormal preponderance of the intellect, the capacity for objective, dramatic representation.

Modern sculpture, whatever it may achieve, is still analogous to modern Latin poetry, and, like this, is a child of imitation, sprung from reminiscences. If it presumes to try to be original, it at once goes astray,

especially upon the bad path of forming according to nature as it lies before it, instead of according to the proportions of the ancients. Canova, Thorwaldsen, and many others may be compared to Johannes Secundus and Owenus. It is the same with architecture, only there it is founded in the art itself, the purely æsthetic part of which is of small compass, and was already exhausted by the ancients; therefore the modern architect can only distinguish himself in the wise application of it; and he ought to know that he removes himself from good taste just so far as he departs from the style and pattern of the Greeks.

The art of the painter, considered only so far as it aims at producing the appearance of reality, may ultimately be referred to the fact that he understands how to separate purely what in seeing is the mere sensation, thus the affection of the retina, *i.e.*, the only directly given effect, from its cause, *i.e.*, the objective external world, the perception of which first rises in the understanding from this effect; whereby, if he has technical skill, he is in a position to produce the same effect in the eye through an entirely different cause, the patches of applied colour, from which then in the understanding of the beholder the same perception again arises through the unavoidable reference of the effect to the ordinary cause.

If we consider how there lies something so entirely idiosyncratic, so thoroughly original, in every human countenance, and that it presents a whole which can only belong to a unity consisting entirely of necessary parts by virtue of which we recognise a known individual out of so many thousands, even after long years, although the possible variations of human features, especially of one race, lie within very narrow limits, we must doubt whether anything of such essential unity and such great originality could ever proceed from any other source than from the mysterious depths of the inner being of nature; but from this it would follow that no artist could be capable of really reproducing the original peculiarity of a human countenance, or even of composing it according to nature from recollection. Accordingly what he produced of this kind would always be only a half true, nay, perhaps an impossible composition; for how should he compose an actual physiognomical unity when the principle of this unity is really unknown to him? Therefore, in the case of every face which has merely been imagined by an artist, we must doubt whether it is in fact a possible face, and whether nature, as the master of all masters, would not show it to be a bungled production by pointing out complete contradictions in it. This

would, of course, lead to the principle that in historical paintings only portraits ought to figure, which certainly would then have to be selected with the greatest care and in some degree idealised. It is well known that great artists have always gladly painted from living models and introduced many portraits.

Although, as is explained in the text, the real end of painting, as of art in general, is to make the comprehension of the (Platonic) Ideas of the nature of the world easier for us, whereby we are at once thrown into the state of pure, *i.e.*, will-less, knowing, there yet belongs to it besides this an independent beauty of its own, which is produced by the mere harmony of the colours, the pleasingness of the grouping, the happy distribution of light and shade, and the tone of the whole picture. This accompanying subordinate kind of beauty furthers the condition of pure knowing, and is in painting what the diction, the metre, and rhyme are in poetry; both are not what is essential, but what acts first and immediately.

I have some further evidence to give in support of my judgment given in the first volume, § 50, on the inadmissibleness of allegory in painting. In the Borghese palace at Rome there is the following picture by Michael Angelo Caravaggio: Jesus, as a child of about ten years old, treads upon the head of a serpent, but entirely without fear and with great calmness; and His mother, who accompanies Him, remains quite as indifferent. Close by stands St. Elizabeth, looking solemnly and tragically up to heaven. Now what could be thought of this kyriological hieroglyphic by a man who had never heard anything about the seed of the woman that should bruise the head of the serpent? At Florence, in the library of the palace Riccardi, we find the following allegory upon the ceiling, painted by Luca Giordano, which is meant to signify that science frees the understanding from the bonds of ignorance: the understanding is a strong man bound with cords, which are just falling off; a nymph holds a mirror in front of him, another hands him a large detached wing; above sits science on a globe, and beside her, with a globe in her hand, the naked truth. At Ludwigsburg, near Stuttgart, there is a picture which shows us time, as Saturn, cutting off with a pair of shears the wings of Cupid. If this is meant to signify that when we grow old love proves unstable, this no doubt has its truth.

The following may serve to strengthen my solution of the problem as to why Laocoon does not cry out. One may practically convince oneself of the faulty effect of the representation of shrieking by the works of the plastic

and pictorial arts, which are essentially dumb, by a picture of the slaughter of the innocents, by Guido Reni, which is to be found in the Academy of Arts at Bologna, and in which this great artist has committed the mistake of painting six shrieking wide-open mouths. Let any one who wants to have this more distinct think of a pantomimic representation on the stage, and in one of the scenes an urgent occasion for one of the players to shriek; if now the dancer who is representing this part should express the shriek by standing for a while with his mouth wide open, the loud laughter of the whole house would bear witness to the absurdity of the thing. Accordingly, since the shrieking of Laocoon had to be avoided for reasons which did not lie in the objects to be represented, but in the nature of the representing art, the task thus arose for the artist so to present this not-shrieking as to make it plausible to us that a man in such a position should not shriek. He solves this problem by representing the bite of the snake, not as having already taken place, nor yet as still threatening, but as just happening now in the side; for thereby the lower part of the body is contracted, and shrieking made impossible. This immediate but only subordinate reason was correctly discovered by Goethe, and is expounded at the end of the eleventh book of his autobiography, and also in the paper on Laocoon in the first part of the Propylæa; but the ultimate, primary reason, which conditions this one, is that which I have set forth. I cannot refrain from remarking that I here stand in the same relation to Goethe as with reference to the theory of colours. In the collection of the Duke of Aremberg at Brussels there is an antique head of Laocoon which was found later. However, the head in the world-renowned group is not a restored one which follows from Goethe's special table of all the restorations of this group, which is given at the end of the first volume of the Propylæa, and is also confirmed by the fact that the head which was found later resembles that of the group very much. Thus we must assume that another antique repetition of the group has existed to which the Aremberg head belonged. In my opinion the latter excels both in beauty and expression that of the group. It has the mouth decidedly wider open than in the group, yet not really to the extent of shrieking.

Chapter XXXVII.[21] On The Æsthetics Of Poetry.

I might give it as the simplest and most correct definition of poetry, that it is the art of bringing the imagination into play by means of words. How it brings this to pass I have shown in the first volume, § 51. A special confirmation of what is said there is afforded by the following passage in a letter of Wieland's to Merck, which has since then been published: "I have spent two days and a half upon a single stanza, in which the whole thing ultimately depended upon a single word which I wanted and could not find. I revolved and turned about the thing and my brain in all directions, because naturally, where a picture was in question, I desired to bring the same definite vision, which floated before my own mind into the mind of my reader also, and for this all often depends, ut nosti, upon a single touch or suggestion or reflex" (*Briefe an Merck*, edited by Wagner, 1835, p. 193). From the fact that the imagination of the reader is the material in which poetry exhibits its pictures, it has the advantage that the fuller development of these pictures and their finer touches, take place in the imagination of every one just as is most suitable to his individuality, his sphere of knowledge, and his humour, and therefore move him in the most lively manner; instead of which plastic and pictorial art cannot so adapt itself, but here one picture, one form, must satisfy all. And yet this will always bear in some respect the stamp of the individuality of the artist or of his model, as a subjective or accidental and inefficient addition; although always less so the more objective, *i.e.*, the more of a genius, the artist is. This, to some extent, explains why works of poetry exercise a much stronger, deeper, and more universal effect than pictures and statues; the latter, for the most part, leave the common people quite cold; and, in general, the plastic arts are those which have the weakest effect. A remarkable proof of this is afforded by the frequent discovery and disclosure of pictures by great masters in private houses and all kinds of localities, where they have been hanging for many generations, not buried and concealed, but merely unheeded, thus without any effect. In my time (1823) there was even discovered in Florence a Madonna of Raphael's, which had hung for a long series of years on the wall of the servants' hall of a palace (in the *Quartiere di S. Spirito*); and this happens among Italians, the nation which is gifted beyond all others with the sense of the beautiful. It shows how little direct and

immediate effect the works of plastic and pictorial art have, and that it requires more culture and knowledge to prize them than the works of all other arts. How unfailingly, on the contrary, a beautiful melody that touches the heart makes its journey round the world, and an excellent poem wanders from people to people. That the great and rich devote their powerful support just to the plastic and pictorial arts, and expend considerable sums upon their works only; nay, at the present day, an idolatry, in the proper sense of the term, gives the value of a large estate for a picture of a celebrated old master — this depends principally upon the rarity of the masterpieces, the possession of which therefore gratifies pride; and then also upon the fact that the enjoyment of them demands very little time and effort, and is ready at any moment, for a moment; while poetry and even music make incomparably harder conditions. Corresponding to this, the plastic and pictorial arts may be dispensed with; whole nations — for example, the Mohammedan peoples — are without them, but no people is without music and poetry.

But the intention with which the poet sets our imagination in motion is to reveal to us the Ideas, *i.e.*, to show us by an example what life and what the world is. The first condition of this is that he himself has known it; according as his knowledge has been profound or superficial so will his poem be. Therefore, as there are innumerable degrees of profoundness and clearness in the comprehension of the nature of things, so are there of poets. Each of these, however, must regard himself as excellent so far as he has correctly represented what he knew, and his picture answers to his original: he must make himself equal with the best, for even in the best picture he does not recognise more than in his own, that is, as much as he sees in nature itself; for his glance cannot now penetrate deeper. But the best himself recognises himself as such in the fact that he sees how superficial was the view of the others, how much lay beyond it which they were not able to repeat, because they did not see it, and how much further his own glance and picture reaches. If he understood the superficial poets as little as they do him, then he would necessarily despair; for just because it requires an extraordinary man to do him justice, but the inferior poets can just as little esteem him as he can them, he also has long to live upon his own approval before that of the world follows it. Meanwhile he is deprived even of his own approval, for he is expected to be very modest. It is, however, as impossible that he who has merit, and knows what it costs, should himself

be blind to it, as that a man who is six feet high should not observe that he rises above others. If from the base of the tower to the summit is 300 feet, then certainly it is just as much from the summit to the base. Horace, Lucretius, Ovid, and almost all the ancients have spoken proudly of themselves, and also Dante, Shakspeare, Bacon of Verulam, and many more. That one can be a great man without observing anything of it is an absurdity of which only hopeless incapacity can persuade itself, in order that it may regard the feeling of its own insignificance as modesty. An Englishman has wittily and correctly observed that merit and modesty have nothing in common except the initial letter.[22] I have always a suspicion about modest celebrities that they may very well be right; and Corneille says directly —

"La fausse humilité ne met plus en crédit:
Je sçais ce que je vaux, et crois ce qu'on m'en dit."

Finally, Goethe has frankly said, "Only good-for-nothings are modest." But the assertion would be still more certain that those who so eagerly demand modesty from others, urge modesty, unceasingly cry, "Only be modest, for God's sake, only be modest!" are positively good-for-nothings, *i.e.*, persons entirely without merit, manufactures of nature, ordinary members of the great mass of humanity. For he who himself has merit also concedes merit — understands himself truly and really. But he who himself lacks all excellence and merit wishes there was no such thing: the sight of it in others stretches him upon the rack; pale, green, and yellow envy consumes his heart: he would like to annihilate and destroy all those who are personally favoured; but if unfortunately he must let them live, it must only be under the condition that they conceal, entirely deny, nay, abjure their advantages. This, then, is the root of the frequent eulogising of modesty. And if the deliverers of these eulogies have the opportunity of suppressing merit as it arises, or at least of hindering it from showing itself or being known, who can doubt that they will do it? For this is the practice of their theory.

Now, although the poet, like every artist, always brings before us only the particular, the individual, what he has known, and wishes by his work to make us know, is the (Platonic) Idea, the whole species; therefore in his images, as it were, the type of human characters and situations will be impressed. The narrative and also the dramatic poet takes the whole particular from life, and describes it accurately in its individuality, but yet

reveals in this way the whole of human existence; for although he seems to have to do with the particular, in truth he is concerned with that which is everywhere and at all times. Hence it arises that sentences, especially of the dramatic poets, even without being general apophthegms, find frequent application in actual life. Poetry is related to philosophy as experience is related to empirical science. Experience makes us acquainted with the phenomenon in the particular and by means of examples, science embraces the whole of phenomena by means of general conceptions. So poetry seeks to make us acquainted with the (Platonic) Ideas through the particular and by means of examples. Philosophy aims at teaching, as a whole and in general, the inner nature of things which expresses itself in these. One sees even here that poetry bears more the character of youth, philosophy that of old age. In fact, the gift of poetry really only flourishes in youth; and also the susceptibility for poetry is often passionate in youth: the youth delights in verses as such, and is often contented with small ware. This inclination gradually diminishes with years, and in old age one prefers prose. By that poetical tendency of youth the sense of the real is then easily spoiled. For poetry differs from reality by the fact that in it life flows past us, interesting and yet painless; while in reality, on the contrary, so long as it is painless it is uninteresting, and as soon as it becomes interesting, it does not remain without pain. The youth who has been initiated into poetry earlier than into reality now desires from the latter what only the former can achieve; this is a principal source of the discomfort which oppresses the most gifted youths.

Metre and rhyme are a fetter, but also a veil which the poet throws round him, and under which he is permitted to speak as he otherwise dared not do; and that is what gives us pleasure. He is only half responsible for all that he says; metre and rhyme must answer for the other half. Metre, or measure, as mere rhythm, has its existence only in time, which is a pure perception a priori, thus, to use Kant’s language, belongs merely to pure sensibility; rhyme, on the other hand, is an affair of sensation, in the organ of hearing, thus of empirical sensibility. Therefore rhythm is a much nobler and more worthy expedient than rhyme, which the ancients accordingly despised, and which found its origin in those imperfect languages which arose from the corruption of earlier ones and in barbarous times. The poorness of French poetry depends principally upon the fact that it is confined to rhyme alone without metre, and it is increased by the fact that in order to conceal its

want of means it has increased the difficulty of rhyming by a number of pedantic laws, such as, for example, that only syllables which are written the same way rhyme, as if it were for the eye and not for the ear that the hiatus is forbidden; that a number of words must not occur; and many such, to all of which the new school of French poetry seeks to put an end. In no language, however, at least on me, does the rhyme make such a pleasing and powerful impression as in Latin; the rhymed Latin poems of the Middle Ages have a peculiar charm. This must be explained from the fact that the Latin language is incomparably more perfect, more beautiful and noble, than any modern language, and now moves so gracefully in the ornaments and spangles which really belong to the latter, and which it itself originally despised.

To serious consideration it might almost appear as high treason against our reason that even the slightest violence should be done to a thought or its correct and pure expression, with the childish intention that after some syllables the same sound of word should be heard, or even that these syllables themselves should present a kind of rhythmical beat. But without such violence very few verses would be made; for it must be attributed to this that in foreign languages verses are much more difficult to understand than prose. If we could see into the secret workshops of the poets, we would find that the thought is sought for the rhyme ten times oftener than the rhyme for the thought; and even when the latter is the case, it is not easily accomplished without pliability on the part of the thought. But the art of verse bids defiance to these considerations, and, moreover, has all ages and peoples upon its side, so great is the power which metre and rhyme exercise upon the feeling, and so effective the mysterious lenocinium which belongs to them. I would explain this from the fact that a happily rhymed verse, by its indescribably emphatic effect, raises the feeling as if the thought expressed in it lay already predestined, nay, performed in the language, and the poet has only had to find it out. Even trivial thoughts receive from rhythm and rhyme a touch of importance; cut a figure in this attire, as among girls plain faces attract the eye by finery. Nay, even distorted and false thoughts gain through versification an appearance of truth. On the other hand, even famous passages from famous poets shrink together and become insignificant when they are reproduced accurately in prose. If only the true is beautiful, and the dearest ornament of truth is nakedness, then a thought which appears true and beautiful in prose will have more true worth

than one which affects us in the same way in verse. Now it is very striking, and well worth investigating, that such trifling, nay, apparently childish, means as metre and rhyme produce so powerful an effect. I explain it to myself in the following manner: That which is given directly to the sense of hearing, thus the mere sound of the words, receives from rhythm and rhyme a certain completeness and significance in itself for it thereby becomes a kind of music; therefore it seems now to exist for its own sake, and no longer as a mere means, mere signs of something signified, the sense of the words. To please the ear with its sound seems to be its whole end, and therefore with this everything seems to be attained and all claims satisfied. But that it further contains a meaning, expresses a thought, presents itself now as an unexpected addition, like words to music — as an unexpected present which agreeably surprises us — and therefore, since we made no demands of this kind, very easily satisfies us; and if indeed this thought is such that, in itself, thus said in prose, it would also be significant, then we are enchanted. I can remember, in my early childhood, that I had delighted myself for a long time with the agreeable sound of verse before I made the discovery that it all also contained meaning and thoughts. Accordingly there is also, in all languages, a mere doggerel poetry almost entirely devoid of meaning. Davis, the Sinologist, in the preface to his translation of the "*Laou-sang-urh*," or "*An Heir in Old Age*" (*London, 1817*), observes that the Chinese dramas partly consist of verses which are sung, and adds: "The meaning of them is often obscure, and, according to the statements of the Chinese themselves, the end of these verses is especially to flatter the ear, and the sense is neglected, and even entirely sacrificed to the harmony." Who is not reminded here of the choruses of many Greek tragedies which are often so hard to make out?

The sign by which one most immediately recognises the genuine poet, both of the higher and lower species, is the unforced nature of his rhymes. They have appeared of themselves as if by divine arrangement; his thoughts come to him already in rhyme. The homely, prosaic man on the contrary, seeks the rhyme for the thought; the bungler seeks the thought for the rhyme. Very often one can find out from a couple of rhymed verses which of the two had the thought and which had the rhyme as its father. The art consists in concealing the latter, so that such lines may not appear almost as mere stuffed out boutsrimés.

According to my feeling (proofs cannot here be given) rhyme is from its nature binary: its effect is limited to one single recurrence of the same sound, and is not strengthened by more frequent repetition. Thus whenever a final syllable has received the one of the same sound its effect is exhausted; the third recurrence of the note acts merely as a second rhyme which accidentally hits upon the same sound, but without heightening the effect; it links itself on to the existing rhyme, yet without combining with it to produce a stronger impression. For the first note does not sound through the second on to the third: therefore this is an æsthetic pleonasm, a double courage which is of no use. Least of all, therefore, do such accumulations of rhymes merit the heavy sacrifices which they cost in the octave rhyme, the terza rima, and the sonnet, and which are the cause of the mental torture under which we sometimes read such productions, for poetical pleasure is impossible under the condition of racking our brains. That the great poetical mind sometimes overcomes even these forms, and moves in them with ease and grace, does not extend to a recommendation of the forms themselves, for in themselves they are as ineffectual as they are difficult. And even in good poets, when they make use of these forms, we frequently see the conflict between the rhyme and the thought, in which now one and now the other gains the victory; thus either the thought is stunted for the sake of the rhyme, or the rhyme has to be satisfied with a weak à peu près. Since this is so, I do not regard it as an evidence of ignorance, but as a proof of good taste, that Shakspeare in his sonnets has given different rhymes to each quatraine. At any rate, their acoustic effect is not in the least diminished by it, and the thought obtains its rights far more than it could have done if it had had to be laced up in the customary Spanish boots.

It is a disadvantage for the poetry of a language if it has many words which cannot be used in prose, and, on the other hand, dare not use certain words of prose. The former is mostly the case in Latin and Italian poetry, and the latter in French, where it has recently been very aptly called, “La bégeulerie de la langue française;” both are to be found less in English, and least in German. For such words belonging exclusively to poetry remain foreign to our heart, do not speak to us directly, and therefore leave us cold. They are a conventional language of poetry, and as it were mere painted sensations instead of real ones: they exclude genuine feeling.

The distinction, so often discussed in our own day, between classic and romantic poetry seems to me ultimately to depend upon the fact that the former knows no other motives than those which are purely human, actual, and natural; the latter, on the other hand, also treats artificial conventional, and imaginary motives as efficient. To such belong the motives which spring from the Christian mythus, also from the chivalrous over-strained fantastical law of honour, further from the absurd and ludicrous Germano-Christian veneration of women, and lastly from doting and mooning hyperphysical amorousness. But even in the best poets of the romantic class, *e.g.*, in Calderon, we can see to what ridiculous distortions of human relations and human nature these motives lead. Not to speak of the Autos, I merely refer to such pieces as “No siempre el peor es cierto” (The worst is not always certain), and “El postrero duelo en España” (The last duel in Spain), and similar comedies en capa y espada: with the elements mentioned there is here further associated the scholastic subtility so often appearing in the conversation which at that time belonged to the mental culture of the higher classes. How decidedly advantageous, on the contrary, is the position of the poetry of the ancients, which always remains true to nature; and the result is that classical poetry has an unconditional, romantic poetry only a conditional, truth and correctness; analogous to Greek and Gothic architecture. Yet, on the other hand, we must remark here that all dramatic or narrative poems which transfer their scene to ancient Greece or Rome lose by this from the fact that our knowledge of antiquity, especially in what concerns the details of life, is insufficient, fragmentary, and not drawn from perception. This obliges the poet to avoid much and to content himself with generalities, whereby he becomes abstract, and his work loses that concreteness and individualisation which is throughout essential to poetry. It is this which gives all such works the peculiar appearance of emptiness and tediousness. Only Shakspeare’s works of this kind are free from it; because without hesitation he has presented, under the names of Greeks and Romans, Englishmen of his own time.

It has been objected to many masterpieces of lyrical poetry, especially some Odes of Horace (see, for example, the second of the third book) and several of Goethe’s songs (for example, “The Shepherd’s Lament”), that they lack proper connection and are full of gaps in the thought. But here the logical connection is intentionally neglected, in order that the unity of the fundamental sensation and mood may take its place, which comes out more

clearly just by the fact that it passes like a thread through the separate pearls, and brings about the quick changes of the objects of contemplation, in the same way as in music the transition from one key to another is brought about by the chord of the seventh, through which the still sounding fundamental note becomes the dominant of the new key. Most distinctly, even exaggeratedly, the quality here described is found in the Canzone of Petrarch which begins, “Mai non vo’ più cantar, com’ io soleva.”

Accordingly, as in the lyrical poem the subjective element predominates, so in the drama, on the contrary, the objective element is alone and exclusively present. Between the two epic poetry in all its forms and modifications, from the narrative romance to the epos proper, has a broad middle path. For although in the main it is objective, yet it contains a subjective element, appearing now more and now less, which finds its expression in the tone, in the form of the delivery, and also in scattered reflections. We do not so entirely lose sight of the poet as in the drama.

The end of the drama in general is to show us in an example what is the nature and existence of man. The sad or the bright side of these can be turned to us in it, or their transitions into each other. But the expression, “nature and existence of man,” already contains the germ of the controversy whether the nature, *i.e.*, the character, or the existence, *i.e.*, the fate, the adventures, the action, is the principal thing. Moreover, the two have grown so firmly together that although they can certainly be separated in conception, they cannot be separated in the representation of them. For only the circumstances, the fate, the events, make the character manifest its nature, and only from the character does the action arise from which the events proceed. Certainly, in the representation, the one or the other may be made more prominent; and in this respect the piece which centres in the characters and the piece which centres in the plot are the two extremes.

The common end of the drama and the epic, to exhibit, in significant characters placed in significant situations, the extraordinary actions brought about by both, will be most completely attained by the poet if he first introduces the characters to us in a state of peace, in which merely their general colour becomes visible, and allows a motive to enter which produces an action, out of which a new and stronger motive arises, which again calls forth a more significant action, which, in its turn, begets new and even stronger motives, whereby, then, in the time suitable to the form of the poem, the most passionate excitement takes the place of the original peace,

and in this now the important actions occur in which the qualities of the characters which have hitherto slumbered are brought clearly to light, together with the course of the world.

Great poets transform themselves into each of the persons to be represented, and speak out of each of them like ventriloquists; now out of the hero, and immediately afterwards out of the young and innocent maiden, with equal truth and naturalness: so Shakspeare and Goethe. Poets of the second rank transform the principal person to be represented into themselves. This is what Byron does; and then the other persons often remain lifeless, as is the case even with the principal persons in the works of mediocre poets.

Our pleasure in tragedy belongs, not to the sense of the beautiful, but to that of the sublime; nay, it is the highest grade of this feeling. For, as at the sight of the sublime in nature we turn away from the interests of the will, in order to be purely perceptive, so in the tragic catastrophe we turn away even from the will to live. In tragedy the terrible side of life is presented to us, the wail of humanity, the reign of chance and error, the fall of the just, the triumph of the wicked; thus the aspect of the world which directly strives against our will is brought before our eyes. At this sight we feel ourselves challenged to turn away our will from life, no longer to will it or love it. But just in this way we become conscious that then there still remains something over to us, which we absolutely cannot know positively, but only negatively, as that which does not will life. As the chord of the seventh demands the fundamental chord; as the colour red demands green, and even produces it in the eye; so every tragedy demands an entirely different kind of existence, another world, the knowledge of which can only be given us indirectly just as here by such a demand. In the moment of the tragic catastrophe the conviction becomes more distinct to us than ever that life is a bad dream from which we have to awake. So far the effect of the tragedy is analogous to that of the dynamical sublime, for like this it lifts us above the will and its interests, and puts us in such a mood that we find pleasure in the sight of what tends directly against it. What gives to all tragedy, in whatever form it may appear, the peculiar tendency towards the sublime is the awakening of the knowledge that the world, life, can afford us no true pleasure, and consequently is not worthy of our attachment. In this consists the tragic spirit: it therefore leads to resignation.

I admit that in ancient tragedy this spirit of resignation seldom appears and is expressed directly. Œdipus Colonus certainly dies resigned and willing; yet he is comforted by the revenge on his country. Iphigenia at Aulis is very willing to die; yet it is the thought of the welfare of Greece that comforts her, and occasions the change of her mind, on account of which she willingly accepts the death which at first she sought to avoid by any means. Cassandra, in the Agamemnon of the great Æschylus, dies willingly, αρκειτω βιος (1306); but she also is comforted by the thought of revenge. Hercules, in the Trachiniæ, submits to necessity, and dies composed, but not resigned. So also the Hippolytus of Euripides, in whose case it surprises us that Artemis, who appears to comfort him, promises him temples and fame, but never points him to an existence beyond life, and leaves him in death, as all gods forsake the dying: — in Christianity they come to him; and so also in Brahmanism and Buddhism, although in the latter the gods are really exotic. Thus Hippolytus, like almost all the tragic heroes of the ancients, shows submission to inevitable fate and the inflexible will of the gods, but no surrender of the will to live itself. As the Stoic equanimity is fundamentally distinguished from Christian resignation by the fact that it teaches only patient endurance and composed expectation of unalterably necessary evil, while Christianity teaches renunciation, surrender of the will; so also the tragic heroes of the ancients show resolute subjection under the unavoidable blows of fate, while Christian tragedy, on the contrary, shows the surrender of the whole will to live, joyful forsaking of the world in the consciousness of its worthlessness and vanity. But I am also entirely of opinion that modern tragedy stands higher than that of the ancients. Shakspeare is much greater than Sophocles; in comparison with Goethe's Iphigenia one might find that of Euripides almost crude and vulgar. The Bacchæ of Euripides is a revolting composition in favour of the heathen priests. Many ancient pieces have no tragic tendency at all, like the Alcestis and Iphigenia in Tauris of Euripides; some have disagreeable, or even disgusting motives, like the Antigone and Philocteles. Almost all show the human race under the fearful rule of chance and error, but not the resignation which is occasioned by it, and delivers from it. All because the ancients had not yet attained to the summit and goal of tragedy, or indeed of the view of life itself.

Although, then, the ancients displayed little of the spirit of resignation, the turning away of the will from life, in their tragic heroes themselves, as

their frame of mind, yet the peculiar tendency and effect of tragedy remains the awakening of that spirit in the beholder, the calling up of that frame of mind, even though only temporarily. The horrors upon the stage hold up to him the bitterness and worthlessness of life, thus the vanity of all its struggle. The effect of this impression must be that he becomes conscious, if only in obscure feeling, that it is better to tear his heart free from life, to turn his will from it, to love not the world nor life; whereby then in his deepest soul, the consciousness is aroused that for another kind of willing there must also be another existence. For if this were not so, then the tendency of tragedy would not be this rising above all the ends and good things of life, this turning away from it and its seductions, and the turning towards another kind of existence, which already lies in this, although an existence which is for us quite inconceivable. How would it, then, in general, be possible that the exhibition of the most terrible side of life, brought before our eyes in the most glaring light, could act upon us beneficently, and afford us a lofty satisfaction? Fear and sympathy, in the excitement of which Aristotle places the ultimate end of tragedy, certainly do not in themselves belong to the agreeable sensations: therefore they cannot be the end, but only the means. Thus the summons to turn away the will from life remains the true tendency of tragedy, the ultimate end of the intentional exhibition of the suffering of humanity, and is so accordingly even where this resigned exaltation of the mind is not shown in the hero himself, but is merely excited in the spectator by the sight of great, unmerited, nay, even merited suffering. Many of the moderns also are, like the ancients, satisfied with throwing the spectator into the mood which has been described, by the objective representation of human misfortune as a whole; while others exhibit this through the change of the frame of mind of the hero himself, effected by suffering. The former give, as it were, only the premisses, and leave the conclusion to the spectator; while the latter give the conclusion, or the moral of the fable, also, as the change of the frame of mind of the hero, and even also as reflection, in the mouth of the chorus, as, for example, Schiller in "The Bride of Messina:" "Life is not the highest good." Let me remark here that the genuine tragic effect of the catastrophe, thus the resignation and exaltation of the mind of the hero which is brought about by it, seldom appears so purely motived and so distinctly expressed as in the opera of "Norma," where it comes in in the duet, "Qual cor tradisti, qual cor perdesti," in which the change of the will is distinctly indicated by

the quietness which is suddenly introduced into the music. In general, this piece — regarded apart altogether from its excellent music, and also from the diction which can only be that of a libretto, and considered only according to its motives and its inner economy — is a highly perfect tragedy, a true pattern of tragic disposition of the motives, tragic progress of the action, and tragic development, together with the effect of these upon the frame of mind of the hero, raising it above the world, and which is then also communicated to the spectator; indeed the effect attained here is the less delusive and the more indicative of the true nature of tragedy that no Christians, nor even Christian ideas, appear in it.

The neglect of the unity of time and place with which the moderns are so often reproached is only a fault when it goes so far that it destroys the unity of the action; for then there only remains the unity of the principal character, as, for example, in Shakspeare's "Henry VIII." But even the unity of the action does not need to go so far that the same thing is spoken of throughout, as in the French tragedies which in general observe this so strictly that the course of the drama is like a geometrical line without breadth. There it is constantly a case of "Only get on! Pensez à votre affaire!" and the thing is expedited and hurried on in a thoroughly business fashion, and no one detains himself with irrelevances which do not belong to it, or looks to the right or the left. The Shakspearian tragedy, on the other hand, is like a line which has also breadth: it takes time, exspatiatur: speeches and even whole scenes occur which do not advance the action, indeed do not properly concern it, by which, however, we get to know the characters or their circumstances more fully, and then understand the action also more thoroughly. This certainly remains the principal thing, yet not so exclusively that we forget that in the last instance what is aimed at is the representation of human nature and existence generally.

The dramatic or epic poet ought to know that he is fate, and should therefore be inexorable, as it is; also that he is the mirror of the human race, and should therefore represent very many bad and sometimes profligate characters, and also many fools, buffoons, and eccentric persons; then also, now and again, a reasonable, a prudent, an honest, or a good man, and only as the rarest exception a truly magnanimous man. In the whole of Homer there is in my opinion no really magnanimous character presented, although many good and honest. In the whole of Shakspeare there may be perhaps a couple of noble, though by no means transcendently noble, characters to be

found; perhaps Cordelia, Coriolanus — hardly more; on the other hand, his works swarm with the species indicated above. But Iffland's and Kotzebue's pieces have many magnanimous characters; while Goldoni has done as I recommended above, whereby he shows that he stands higher. On the other hand, Schiller's "Minna von Barnhelm" labours under too much and too universal magnanimity; but so much magnanimity as the one Marquis Posa displays is not to be found in the whole of Goethe's works together. There is, however, a small German piece called "Duty for Duty's Sake" (a title which sounds as if it had been taken from the Critique of Practical Reason), which has only three characters, and yet all the three are of most transcendent magnanimity.

The Greeks have taken for their heroes only royal persons; and so also for the most part have the moderns. Certainly not because the rank gives more worth to him who is acting or suffering; and since the whole thing is just to set human passions in play, the relative value of the objects by which this happens is indifferent, and peasant huts achieve as much as kingdoms. Moreover, civic tragedy is by no means to be unconditionally rejected. Persons of great power and consideration are yet the best adapted for tragedy on this account, that the misfortune in which we ought to recognise the fate of humanity must have a sufficient magnitude to appear terrible to the spectator, whoever he may be. Euripides himself says, "φευ, φευ, τα μεγαλα, μεγαλα και πασχει κακα" (*Stob. Flor.*, vol. ii. p. 299). Now the circumstances which plunge a citizen family into want and despair are in the eyes of the great or rich, for the most part, very insignificant, and capable of being removed by human assistance, nay, sometimes even by a trifle: such spectators, therefore, cannot be tragically affected by them. On the other hand, the misfortunes of the great and powerful are unconditionally terrible, and also accessible to no help from without; for kings must help themselves by their own power, or fall. To this we have to add that the fall is greatest from a height. Accordingly persons of the rank of citizens lack height to fall from.

If now we have found the tendency and ultimate intention of tragedy to be a turning to resignation, to the denial of the will to live, we shall easily recognise in its opposite, comedy, the incitement to the continued assertion of the will. It is true the comedy, like every representation of human life, without exception, must bring before our eyes suffering and adversity; but it presents it to us as passing, resolving itself into joy, in general mingled with

success, victory, and hopes, which in the end preponderate; moreover, it brings out the inexhaustible material for laughter of which life, and even its adversities themselves are filled, and which under all circumstances ought to keep us in a good humour. Thus it declares, in the result, that life as a whole is thoroughly good, and especially is always amusing. Certainly it must hasten to drop the curtain at the moment of joy, so that we may not see what comes after; while the tragedy, as a rule, so ends that nothing can come after. And moreover, if once we contemplate this burlesque side of life somewhat seriously, as it shows itself in the naïve utterances and gestures which trifling embarrassment, personal fear, momentary anger, secret envy, and many similar emotions force upon the forms of the real life that mirrors itself here, forms which deviate considerably from the type of beauty, then from this side also, thus in an unexpected manner, the reflective spectator may become convinced that the existence and action of such beings cannot itself be an end; that, on the contrary, they can only have attained to existence by an error, and that what so exhibits itself is something which had better not be.

Chapter XXXVIII.[23] On History.

In the passage of the first volume referred to below I have fully shown that more is achieved for our knowledge of mankind by poetry than by history, and why this is so; inasmuch as more real instruction was to be expected from the former than from the latter. Aristotle has also confessed this, for he says: "και φιλοσοφωτερον και σπουδαιοτερον ποιησις ἱστοριας εστιν" (et res magis philosophica, et melior poësis est quam historia[24]), *De poët.*, c. 9. Yet, in order to cause no misunderstanding as to the value of history, I wish here to express my thoughts about it.

In every class and species of things the facts are innumerable, the individuals infinite in number, the variety of their differences unapproachable. At the first glance at them the curious mind becomes giddy; however much it investigates, it sees itself condemned to ignorance. But then comes science: it separates the innumerable multitude, arranges it under generic conceptions, these again under conceptions of species, whereby it opens the path to a knowledge of the general and the particular, which also comprehends the innumerable individuals, for it holds good of all without one being obliged to consider each particular for itself. Thus it promises satisfaction to the investigating mind. Then all sciences place themselves together, and above the real world of individual things, as that which they have divided among them. Over them all, however, moves philosophy, as the most general, and therefore important, rational knowledge, which promises the conclusions for which the others have only prepared the way. History alone cannot properly enter into that series, since it cannot boast of the same advantage as the others, for it lacks the fundamental characteristic of science, the subordination of what is known, instead of which it can only present its co-ordination. Therefore there is no system of history, as there is of every other science. It is therefore certainly rational knowledge, but it is not a science. For it never knows the particular by means of the general, but must comprehend the particular directly, and so, as it were, creeps along the ground of experience; while the true sciences move above it, because they have obtained comprehensive conceptions by means of which they command the particular, and, at least within certain limits, anticipate the possibility of things within their sphere, so that they can be at ease even about what may yet have to come. The

sciences, since they are systems of conceptions, speak always of species; history speaks of individuals. It would accordingly be a science of individuals, which is a contradiction. It also follows that the sciences all speak of that which always is as history, on the other hand, of that which is once, and then no more. Since, further, history has to do with the absolutely particular and individuals, which from its nature is inexhaustible, it knows everything only imperfectly and half. Besides, it must also let itself be taught by every new day in its trivial commonplaceness what as yet it did not know at all. If it should be objected that in history also there is subordination of the particular under the general, because the periods, the governments, and other general changes, or political revolutions, in short, all that is given in historical tables, is the general, to which the special subordinates itself, this would rest upon a false comprehension of the conception of the general. For the general in history here referred to is merely subjective, *i.e.*, its generality springs merely from the inadequacy of the individual knowledge of the things, but not objective, *i.e.*, a conception in which the things would actually already be thought together. Even the most general in history is in itself only a particular and individual, a long period of time, or an important event; therefore the special is related to this as the part to the whole, but not as the case to the rule; which, on the contrary, takes place in all the sciences proper because they afford conceptions and not mere facts. On this account in these sciences by a correct knowledge of the general we can determine with certainty the particular that arises. If, for example, I know the laws of the triangle in general, I can then also tell what must be the properties of the triangle laid before me; and what holds good of all mammals, for example, that they have double ventricles of the heart, exactly seven cervical vertebræ, lungs, diaphragm, bladder, five senses, &c., I can also assert of the strange bat which has just been caught, before dissecting it. But not so in history, where the general is no objective general of the conception, but merely a subjective general of my knowledge, which can only be called general inasmuch as it is superficial. Therefore I may always know in general of the Thirty Years' War that it was a religious war, waged in the seventeenth century; but this general knowledge does not make me capable of telling anything more definite about its course. The same opposition is also confirmed by the fact that in the real sciences the special and individual is that which is most certain, because it rests upon immediate apprehension;

the general truths, again, are only abstracted from it; therefore something false may be more easily assumed in the latter. But in history, conversely, the most general is the most certain; for example, the periods, the succession of the kings, the revolutions, wars, and treaties of peace; the particulars, again, of the events and their connection is uncertain, and becomes always more so the further one goes into details. Therefore history is the more interesting the more special it is, but the less to be trusted, and approaches then in every respect to the romance. For the rest, what importance is to be attached to the boasted pragmatic teaching of history he will best be able to judge who remembers that sometimes it was only after twenty years that he understood the events of his own life in their true connection, although the data for this were fully before him, so difficult is the combination of the action of the motives under the constant interferences of chance and the concealment of the intentions. Since now history really always has for its object only the particular, the individual fact, and regards this as the exclusively real, it is the direct opposite and counterpart of philosophy, which considers things from the most general point of view, and has intentionally the general as its object, which remains identical in every particular; therefore in the particular philosophy sees only the general, and recognises the change in its manifestation as unessential: φιλοκαθολου γαρ ὁ φιλοσοφος (generalium amator philosophus). While history teaches us that at every time something else has been, philosophy tries to assist us to the insight that at all times exactly the same was, is, and shall be. In truth, the essence of human life, as of nature in general, is given complete in every present time, and therefore only requires depth of comprehension in order to be exhaustively known. But history hopes to make up for depth by length and breadth; for it every present time is only a fragment which must be supplemented by the past, the length of which is, however, infinite, and to which again an infinite future is joined. Upon this rests the opposition between philosophical and historical minds; the former want to go to the bottom, the latter want to go through the whole series. History shows on every side only the same under different forms; but whoever does not come to know this in one or a few will hardly attain to a knowledge of it by going through all the forms. The chapters of the history of nations are at bottom only distinguished by the names and dates; the really essential content is everywhere the same.

Now since the material of art is the Idea, and the material of science the concept, we see both occupied with that which always exists and constantly in the same manner, not something which now is and now is not, now is thus and now otherwise; therefore both have to do with that which Plato set up as the exclusive object of real rational knowledge. The material of history, on the other hand, is the particular in its particularity and contingency, which at one time is, and then for ever is no more, the transient complexities of a human world moved like clouds in the wind, a world which is often entirely transformed by the most trifling accident. From this point of view the material of history appears to us as scarcely a worthy object of the serious and painful consideration of the human mind, the human mind which, just because it is so transitory, ought to choose for its consideration that which passes not away.

Finally, as regards the endeavour — specially introduced by the Hegelian pseudo-philosophy, everywhere so pernicious and stupefying to the mind — to comprehend the history of the world as a planned whole, or, as they call it, “to construe it organically,” a crude and positive realism lies at its foundation, which takes the phenomenon for the inner being of the world, and imagines that this phenomenon, its forms and events, are the chief concern; in which it is secretly supported by certain mythological notions which it tacitly assumes: otherwise one might ask for what spectators such a comedy was really produced. For, since only the individual, and not the human race, has actual, immediate unity of consciousness, the unity of the course of life of the race is a mere fiction. Besides, as in nature only the species are real, and the genera are mere abstractions, so in the human race only the individuals and their course of life are real, the peoples and their lives mere abstractions. Finally, constructive histories, guided by a positive optimism, always ultimately end in a comfortable, rich, fat State, with a well-regulated constitution, good justice and police, useful arts and industries, and, at the most, in intellectual perfection; for this, in fact, is alone possible, since what is moral remains essentially unaltered. But it is the moral element which, according to the testimony of our inmost consciousness, is the whole concern: and this lies only in the individual as the tendency of his will. In truth, only the life of each individual has unity, connection, and true significance: it is to be regarded as an instruction, and the meaning of it is moral. Only the incidents of our inner life, since they concern the will, have true reality, and are actual events; because the will

alone is the thing in itself. In every microcosm lies the whole macrocosm, and the latter contains nothing more than the former. Multiplicity is phenomenal, and external events are mere configurations of the phenomenal world, and have therefore directly neither reality nor significance, but only indirectly through their relation to the wills of the individuals. The endeavour to explain and interpret them directly is accordingly like the endeavour to see in the forms of the clouds groups of men and animals. What history narrates is in fact only the long, heavy, and confused dream of humanity.

The Hegelians, who regard the philosophy of history as indeed the chief end of all philosophy, are to be referred to Plato, who unweariedly repeats that the object of philosophy is that which is unchangeable and always remains, not that which now is thus and now otherwise. All those who set up such constructions of the course of the world, or, as they call it, of history, have failed to grasp the principal truth of all philosophy, that what is is at all times the same, all becoming and arising are only seeming; the Ideas alone are permanent; time ideal. This is what Plato holds, this is what Kant holds. One ought therefore to seek to understand what exists, what really is, to-day and always, *i.e.*, to know the Ideas (in Plato's sense). Fools, on the contrary, imagine that something must first become and happen. Therefore they concede to history the chief place in their philosophy, and construct it according to a preconceived plan of the world, according to which everything is ordered for the best, which is then supposed finaliter to appear, and will be a glorious thing. Accordingly they take the world as perfectly real, and place the end of it in the poor earthly happiness, which, however much it may be fostered by men and favoured by fate, is a hollow, deceptive, decaying, and sad thing, out of which neither constitutions and legal systems nor steam-engines and telegraphs can ever make anything that is essentially better. The said philosophers and glorifiers of history are accordingly simple realists, and also optimists and eudæmonists, consequently dull fellows and incarnate philistines; and besides are really bad Christians, for the true spirit and kernel of Christianity, as also of Brahmanism and Buddhism, is the knowledge of the vanity of earthly happiness, the complete contempt for it, and the turning away from it to an existence of another, nay, an opposite, kind. This, I say, is the spirit and end of Christianity, the true "humour of the matter;" and not, as they imagine,

monotheism; therefore even atheistic Buddhism is far more closely related to Christianity than optimistic Judaism or its variety Islamism.

A true philosophy of history ought not therefore to consider, as all these do, what (to use Plato's language) always becomes and never is, and hold this to be the true nature of things; but it ought to fix its attention upon that which always is and never becomes nor passes away. Thus it does not consist in raising the temporal ends of men to eternal and absolute ends, and then with art and imagination constructing their progress through all complications; but in the insight that not only in its development, but in its very nature, history is mendacious; for, speaking of mere individuals and particular events, it pretends always to relate something different, while from beginning to end it repeats always the same thing under different names and in a different dress. The true philosophy of history consists in the insight that in all these endless changes and their confusion we have always before us only the same, even, unchanging nature, which to-day acts in the same way as yesterday and always; thus it ought to recognise the identical in all events, of ancient as of modern times, of the east as of the west; and, in spite of all difference of the special circumstances, of the costume and the customs, to see everywhere the same humanity. This identical element which is permanent through all change consists in the fundamental qualities of the human heart and head — many bad, few good. The motto of history in general should run: Eadem, sed aliter. If one has read Herodotus, then in a philosophical regard one has already studied history enough. For everything is already there that makes up the subsequent history of the world: the efforts, action, sufferings, and fate of the human race as it proceeds from the qualities we have referred to, and the physical earthly lot.

If in what has been said we have recognised that history, regarded as a means for the knowledge of the nature of man, is inferior to poetry; then, that it is not in the proper sense a science; finally, that the endeavour to construct it as a whole with beginning, middle, and end, together with a significant connection, is vain, and based upon misunderstanding: it would look as if we wished to deny it all value if we did not show in what its value consists. Really, however, there remains for it, after this conquest by art and rejection by science, a quite special province, different from both, in which it exists most honourably.

What reason is to the individual that is history to the human race. By virtue of reason, man is not, like the brute, limited to the narrow,

perceptible present, but also knows the incomparably more extended past, with which it is linked, and out of which it has proceeded; and only thus has he a proper understanding of the present itself, and can even draw inferences as to the future. The brute, on the other hand, whose knowledge, devoid of reflection, is on this account limited to the present, even when it is tamed, moves about among men ignorant, dull, stupid, helpless, and dependent. Analogous to this is the nation that does not know its own history, is limited to the present of the now living generation, and therefore does not understand itself and its own present, because it cannot connect it with a past, and explain it from this; still less can it anticipate the future. Only through history does a nation become completely conscious of itself. Accordingly history is to be regarded as the rational consciousness of the human race, and is to the race what the reflected and connected consciousness is to the individual who is conditioned by reason, a consciousness through the want of which the brute is confined to the narrow, perceptible present. Therefore every gap in history is like a gap in the recollective self-consciousness of a man; and in the presence of a monument of ancient times which has outlived the knowledge of itself, as, for example, the Pyramids, or temples and palaces in Yucatan, we stand as senseless and stupid as the brute in the presence of the action of man, in which it is implicated in his service; or as a man before something written in an old cipher of his own, the key to which he has forgotten; nay, like a somnambulist who finds before him in the morning what he has done in his sleep. In this sense, then, history is to be regarded as the reason, or the reflected consciousness, of the human race, and takes the place of an immediate self-consciousness common to the whole race, so that only by virtue of it does the human race come to be a whole, come to be a humanity. This is the true value of history, and accordingly the universal and predominating interest in it depends principally upon the fact that it is a personal concern of the human race. Now, what language is for the reason of individuals, as an indispensable condition of its use, writing is for the reason of the whole race here pointed out; for only with this does its real existence begin, as that of the individual reason begins first with language. Writing serves to restore unity to the consciousness of the human race, which is constantly interrupted by death, and therefore fragmentary; so that the thought which has arisen in the ancestor is thought out by his remote descendant; it finds a remedy for the breaking up of the human race and its

consciousness into an innumerable number of ephemeral individuals, and so bids defiance to the ever hurrying time, in whose hand goes forgetfulness. As an attempt to accomplish this we must regard not only written, but also stone monuments, which in part are older than the former. For who will believe that those who, at incalculable cost, set in action the human powers of many thousands for many years in order to construct the pyramids, monoliths, rock tombs, obelisks, temples, and palaces which have already existed for thousands of years, could have had in view the short span of their own life, too short to let them see the finishing of the construction, or even the ostensible end which the ignorance of the many required them to allege? Clearly their real end was to speak to their latest descendants, to put themselves in connection with these, and so to establish the unity of the consciousness of humanity. The buildings of the Hindus, the Egyptians, even the Greeks and Romans, were calculated to last several thousand years, because through higher culture their horizon was a wider one; while the buildings of the Middle Ages and of modern times have only been intended, at the most, to last a few centuries; which, however, is also due to the fact that men trusted more to writing after its use had become general, and still more since from its womb was born the art of printing. Yet even in the buildings of more recent times we see the desire to speak to posterity; and, therefore, it is shameful if they are destroyed or disfigured in order to serve low utilitarian ends. Written monuments have less to fear from the elements, but more to fear from barbarians, than stone ones; they accomplish far more. The Egyptians wished to combine the two, for they covered their stone monuments with hieroglyphics, nay, they added paintings in case the hieroglyphics should no longer be understood.

Chapter XXXIX.[25] On The Metaphysics Of Music.

The outcome, or result, of my exposition of the peculiar significance of this wonderful art, which is given in the passage of the first volume referred to below, and which will here be present to the mind of the reader, was, that there is indeed no resemblance between its productions and the world as idea, *i.e.*, the world of nature, but yet there must be a distinct parallelism, which was then also proved. I have yet to add some fuller particulars with regard to this parallelism, which are worthy of attention.

The four voices, or parts, of all harmony, the bass, the tenor, the alto, and the soprana, or the fundamental note, the third, the fifth, and the octave, correspond to the four grades in the series of existences, the mineral kingdom, the vegetable kingdom, the brute kingdom, and man. This receives an additional and striking confirmation in the fundamental rule of music, that the bass must be at a much greater distance below the three upper parts than they have between themselves; so that it must never approach nearer to them than at the most within an octave of them, and generally remains still further below them. Hence, then, the correct triad has its place in the third octave from the fundamental note. Accordingly the effect of extended harmony, in which the bass is widely separated from the other parts, is much more powerful and beautiful than that of close harmony, in which it is moved up nearer to them, and which is only introduced on account of the limited compass of the instruments. This whole rule, however, is by no means arbitrary, but has its root in the natural source of the tonal system; for the nearest consonant intervals that sound along with the fundamental note by means of its vibrations are the octave and its fifth. Now, in this rule we recognise the analogue of the fundamental characteristic of nature on account of which organised beings are much more nearly related to each other than to the inanimate, unorganised mass of the mineral kingdom, between which and them exists the most definite boundary and the widest gulf in the whole of nature. The fact that the high voice which sings the melody is yet also an integral part of the harmony, and therein accords even with the deepest fundamental bass, may be regarded as the analogue of the fact that the same matter which in a human organism is the supporter of the Idea of man must yet also exhibit and support the Ideas of gravitation and chemical qualities, that is, of the lowest grades of the objectification of will.

That music acts directly upon the will, *i.e.*, the feelings, passions, and emotions of the hearer, so that it quickly raises them or changes them, may be explained from the fact that, unlike all the other arts, it does not express the Ideas, or grades of the objectification of the will, but directly the will itself.

As surely as music, far from being a mere accessory of poetry, is an independent art, nay, the most powerful of all the arts, and therefore attains its ends entirely with means of its own, so surely does it not stand in need of the words of the song or the action of an opera. Music as such knows the tones or notes alone, but not the causes which produce these. Accordingly, for it even the human voice is originally and essentially nothing else than a modified tone, just like that of an instrument; and, like every other tone, it has the special advantages and disadvantages which are a consequence of the instrument that produces it. Now, in this case, that this same instrument, as the organ of speech, also serves to communicate conceptions is an accidental circumstance, which music can certainly also make use of, in order to enter into a connection with poetry; but it must never make this the principal matter, and concern itself entirely with the expression of what for the most part, nay (as Diderot gives us to understand in *Le Neveu de Rameau*), essentially are insipid verses. The words are and remain for the music a foreign addition, of subordinate value, for the effect of the tones is incomparably more powerful, more infallible, and quicker than that of the words. Therefore, if words become incorporated in music, they must yet assume an entirely subordinate position, and adapt themselves completely to it. But the relation appears reversed in the case of the given poetry, thus the song or the libretto of an opera to which music is adapted. For the art of music at once shows in these its power and higher fitness, disclosing the most profound ultimate and secret significance of the feeling expressed in the words or the action presented in the opera, giving utterance to their peculiar and true nature, and teaching us the inmost soul of the actions and events whose mere clothing and body is set before us on the stage. With regard to this superiority of the music, and also because it stands to the libretto and the action in the relation of the universal to the particular, of the rule to the example, it might perhaps appear more fitting that the libretto should be written for the music than that the music should be composed for the libretto. However, in the customary method, the words and actions of the libretto lead the composer to the affections of the will which lie at their

foundation, and call up in him the feelings to be expressed; they act, therefore, as a means of exciting his musical imagination. Moreover, that the addition of poetry to music is so welcome to us, and a song with intelligible words gives us such deep satisfaction, depends upon the fact that in this way our most direct and most indirect ways of knowing are called into play at once and in connection. The most direct is that for which music expresses the emotions of the will itself, and the most indirect that of conceptions denoted by words. When the language of the feelings is in question the reason does not willingly sit entirely idle. Music is certainly able with the means at its own disposal to express every movement of the will, every feeling; but by the addition of words we receive besides this the objects of these feelings, the motives which occasion them. The music of an opera, as it is presented in the score, has a completely independent, separate, and, as it were, abstract existence for itself, to which the incidents and persons of the piece are foreign, and which follows its own unchanging rules; therefore it can produce its full effect without the libretto. But this music, since it was composed with reference to the drama, is, as it were, the soul of the latter; for, in its connection with the incidents, persons, and words, it becomes the expression of the inner significance of all those incidents, and of their ultimate and secret necessity which depends upon this significance. The pleasure of the spectator, unless he is a mere gaper, really depends upon an indistinct feeling of this. Yet in the opera music also shows its heterogeneous nature and higher reality by its entire indifference to the whole material of the incidents; in consequence of which it everywhere expresses the storm of the passions and the pathos of the feelings in the same way, and its tones accompany the piece with the same pomp, whether Agamemnon and Achilles or the dissensions of a bourgeois family form its material. For only the passions, the movements of the will, exist for it, and, like God, it sees only the hearts. It never assimilates itself to the natural; and therefore, even when it accompanies the most ludicrous and extravagant farces of the comic opera, it still preserves its essential beauty, purity, and sublimity; and its fusion with these incidents is unable to draw it down from its height, to which all absurdity is really foreign. Thus the profound and serious significance of our existence hangs over the farce and the endless miseries of human life, and never leaves it for a moment.

If we now cast a glance at purely instrumental music, a symphony of Beethoven presents to us the greatest confusion, which yet has the most

perfect order at its foundation, the most vehement conflict, which is transformed the next moment into the most beautiful concord. It is rerum concordia discors, a true and perfect picture of the nature of the world which rolls on in the boundless maze of innumerable forms, and through constant destruction supports itself. But in this symphony all human passions and emotions also find utterance; joy, sorrow, love, hatred, terror, hope, &c., in innumerable degrees, yet all, as it were, only in abstracto, and without any particularisation; it is their mere form without the substance, like a spirit world without matter. Certainly we have a tendency to realise them while we listen, to clothe them in imagination with flesh and bones, and to see in them scenes of life and nature on every hand. Yet, taken generally, this is not required for their comprehension or enjoyment, but rather imparts to them a foreign and arbitrary addition: therefore it is better to apprehend them in their immediacy and purity.

Since now, in the foregoing remarks, and also in the text, I have considered music only from the metaphysical side, that is, with reference to the inner significance of its performances, it is right that I should now also subject to a general consideration the means by which, acting upon our mind, it brings these about; therefore that I should show the connection of that metaphysical side of music, and the physical side, which has been fully investigated, and is well known, I start from the theory which is generally known, and has by no means been shaken by recent objections, that all harmony of the notes depends upon the coincidence of their vibrations, which when two notes sound together occurs perhaps at every second, or at every third, or at every fourth vibration, according to which, then, they are the octave, the fifth, or the fourth of each other, and so on. So long as the vibrations of two notes have a rational relation to each other, which can be expressed in small numbers, they can be connected together in our apprehension through their constantly recurring coincidence: the notes become blended, and are thereby in consonance. If, on the other hand, that relation is an irrational one, or one which can only be expressed in larger numbers, then no coincidence of the vibrations which can be apprehended occurs, but obstrepunt sibi perpetuo, whereby they resist being joined together in our apprehension, and accordingly are called a dissonance. Now, according to this theory, music is a means of making rational and irrational relations of numbers comprehensible, not like arithmetic by the help of the concept, but by bringing them to a knowledge which is perfectly directly and

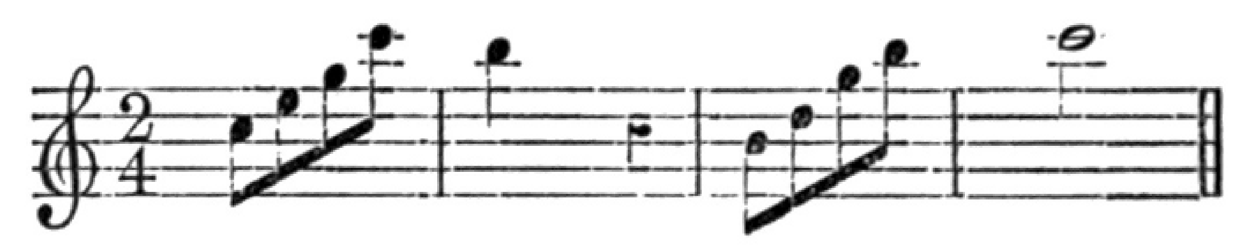
simultaneously sensible. Now the connection of the metaphysical significance of music with this its physical and arithmetical basis depends upon the fact that what resists our apprehension, the irrational relation, or the dissonance, becomes the natural type of what resists our will; and, conversely, the consonance, or the rational relation, which easily adapts itself to our apprehension, becomes the type of the satisfaction of the will. And further, since that rational and irrational element in the numerical relations of the vibrations admits of innumerable degrees, shades of difference, sequences, and variations, by means of it music becomes the material in which all the movements of the human heart, *i.e.*, of the will, movements whose essential nature is always satisfaction and dissatisfaction, although in innumerable degrees, can be faithfully portrayed and rendered in all their finest shades and modifications, which takes place by means of the invention of the melody. Thus we see here the movements of the will transferred to the province of the mere idea, which is the exclusive scene of the achievements of the fine arts, for they absolutely demand that the will itself shall not interfere, and that we shall conduct ourselves as pure knowing subjects. Therefore the affections of the will itself, thus actual pain and actual pleasure, must not be excited, but only their substitutes, that which is agreeable to the intellect, as a picture of the satisfaction of the will, and that which is more or less repugnant to it, as a picture of greater or less pain. Only thus does music never cause us actual sorrow, but even in its most melancholy strains is still pleasing, and we gladly hear in its language the secret history of our will, and all its emotions and strivings, with their manifold protractions, hindrances, and griefs, even in the saddest melodies. When, on the other hand, in reality and its terrors, it is our will itself that is roused and tormented, we have not then to do with tones and their numerical relations, but are rather now ourselves the trembling string that is stretched and twanged.

But, further, because, in consequence of the physical theory which lies at its foundation, the musical quality of the notes is in the proportion of the rapidity of their vibrations, but not in their relative strength, the musical ear always follows by preference, in harmony, the highest note, not the loudest. Therefore, even in the case of the most powerful orchestral accompaniment, the soprano comes out clearly, and thus receives a natural right to deliver the melody. And this is also supported by its great flexibility, which depends upon the same rapidity of the vibrations, and shows itself in the ornate

passages, whereby the soprano becomes the suitable representative of the heightened sensibility, susceptible to the slightest impression, and determinable by it, consequently of the most highly developed consciousness standing on the uppermost stage of the scale of being. Its opposite, from converse causes, is the bass, inflexible, rising and falling only in great intervals, thirds, fourths, and fifths, and also at every step guided by rigid rules. It is therefore the natural representative of the inorganic kingdom of nature, which is insensible, insusceptible to fine impressions, and only determinable according to general laws. It must indeed never rise by one tone, for example, from a fourth to a fifth, for this produces in the upper parts the incorrect consecutive fifths and octaves; therefore, originally and in its own nature, it can never present the melody. If, however, the melody is assigned to it, this happens by means of counterpoint, *i.e.*, it is an inverted bass — one of the upper parts is lowered and disguised as a bass; properly speaking, it then requires a second fundamental bass as its accompaniment. This unnaturalness of a melody lying in the bass is the reason why bass airs, with full accompaniment, never afford us pure, undisturbed pleasure, like the soprano air, which, in the connection of harmony, is alone natural. We may remark in passing that such a melodious bass, forcibly obtained by inversion, might, in keeping with our metaphysic of music, be compared to a block of marble to which the human form has been imparted: and therefore it is wonderfully suitable to the stone guest in "Don Juan."

But now we shall try to get somewhat nearer the foundation of the genesis of melody, which can be accomplished by analysing it into its constituent parts, and in any case will afford us the pleasure which arises from bringing to abstract and distinct consciousness what every one knows in the concrete, so that it gains the appearance of novelty.

Melody consists of two elements, the one rhythmical, the other harmonious. The former may also be described as the quantitative, the latter as the qualitative element, since the first is concerned with the duration, and the second with the pitch of the notes. In the writing of music the former depends upon the perpendicular, and the latter upon the horizontal lines. Purely arithmetical relations, thus relations of time, lie at the foundation of both; in the one case the relative duration of the notes, in the other the relative rapidity of their vibrations. The rhythmical element is the essential; for it can produce a kind of melody of itself alone, and without the other, as, for example, on the drum; yet complete melody requires both elements. It



consists in an alternating disunion and reconciliation of them, as I shall show immediately; but first, since I have already spoken of the harmonious element in what has been said, I wish to consider the rhythmical element somewhat more closely.

Rhythm is in time what symmetry is in space, division into equal parts corresponding to each other. First, into larger parts, which again fall into smaller parts, subordinate to the former. In the series of the arts given by me architecture and music are the two extreme ends. Moreover, according to their inner nature, their power, the extent of their spheres, and their significance, they are the most heterogeneous, indeed true antipodes. This opposition extends even to the form of their appearance, for architecture is in space alone, without any connection with time; and music is in time alone, without any connection with space.[26] Now hence springs their one point of analogy, that as in architecture that which orders and holds together is symmetry, in music it is rhythm, and thus here also it holds true that extremes meet. As the ultimate constituent parts of a building are the exactly similar stones, so the ultimate constituent parts of a musical composition are the exactly similar beats; yet by being weak or strong, or in general by the measure, which denotes the species of time, these are divided into equal parts, which may be compared to the dimensions of the stone. The musical period consists of several bars, and it has also two equal parts, one rising, aspiring, generally going to the dominant, and one sinking, quieting, returning to the fundamental note. Two or several periods constitute a part, which in general is also symmetrically doubled by the sign of repetition; two parts make a small piece of music, or only a movement of a larger piece; and thus a concerto or sonata usually consists of three movements, a symphony of four, and a mass of five. Thus we see the musical composition bound together and rounded off as a whole, by symmetrical distribution and repeated division, down to the beats and their fractions, with thorough subordination, superordination, and co-ordination of its members, just as a building is connected and rounded off by its symmetry. Only in the latter that is exclusively in space which in the former is exclusively in time. The mere feeling of this analogy has in the last thirty years called forth the oft-repeated, daring witticism, that architecture is frozen music. The origin of this can be traced to Goethe; for, according to Eckermann's "Conversations," vol. ii. p. 88, he said: "I have found among my papers a page on which I call architecture a rigidified music; and really there is something in it; the mood

which is produced by architecture approaches the effect of music.” Probably he let fall this witticism much earlier in conversation, and in that case it is well known that there were never wanting persons to pick up what he so let fall that they might afterwards go about decked with it. For the rest, whatever Goethe may have said, the analogy of music and architecture, which is here referred by me to its sole ground, the analogy of rhythm with symmetry, extends accordingly only to the outward form, and by no means to the inner nature of the two arts, which is entirely different. Indeed it would be absurd to wish to put on the same level in essential respects the most limited and the weakest of all the arts, and the most far-reaching and powerful. As an amplification of the analogy pointed out, we might add further, that when music, as it were in a fit of desire for independence, seizes the opportunity of a pause to free itself from the control of rhythm, to launch out into the free imagination of an ornate cadenza, such a piece of music divested of all rhythm is analogous to the ruin which is divested of symmetry, and which accordingly may be called, in the bold language of the witticism, a frozen cadenza.

After this exposition of rhythm, I have now to show how the nature of melody consists in the constantly renewed disunion and reconciliation of the rhythmical, and the harmonious elements of it. Its harmonious element has as its assumption the fundamental note, as the rhythmical element has the species of time, and consists in a wandering from it through all the notes of the scale, until by shorter or longer digressions it reaches a harmonious interval, generally the dominant or sub-dominant, which affords it an incomplete satisfaction; and then follows, by a similarly long path, its return to the fundamental note, with which complete satisfaction appears. But both must so take place that the attainment of the interval referred to and the return to the fundamental note correspond with certain favourite points of the rhythm, otherwise it will not work. Thus, as the harmonious succession of sounds requires certain notes, first of all the tonic, next to it the dominant, and so on, so rhythm, on its part, requires certain points of time, certain numbered bars, and certain parts of these bars, which are called strong or good beats, or the accented parts of the bar, in opposition to the weak or bad beats, or unaccented parts of the bar. Now the disunion of these two fundamental elements consists in this, that because the demand of one is satisfied that of the other is not; and their reconciliation consists in this, that both are satisfied at once and together. That wandering of the notes until they

find a more or less harmonious interval must so take place that this interval is attained only after a definite number of bars, and also at an accented part of the bar, and in this way becomes for it a kind of resting-point; and similarly the return to the keynote must take place after a like number of bars, and also at an accented part of the bar, and thus complete satisfaction is then attained. So long as this required coincidence of the satisfaction of both elements is not attained, the rhythm, on the one hand, may follow its regular course, and, on the other hand, the required notes may occur often enough, but yet they will remain entirely without that effect through which melody arises. The following very simple example may serve to illustrate this: —

Here the harmonious sequence of notes finds the keynote just at the end of the first bar; but it does not receive any satisfaction from this, because the rhythm is caught at the least accented part of the bar. Immediately afterwards, in the second bar, the rhythm has the accented part of the bar, but the sequence of notes has arrived at the seventh. Thus here the two elements of melody are entirely disunited; and we feel disquieted. In the second half of the period everything is reversed, and in the last note they are reconciled. This kind of thing can be shown in every melody, although generally in a much more extended form. Now the constant disunion and reconciliation of its two elements which there takes place is, when metaphysically considered, the copy of the origination of new wishes, and then of their satisfaction. Thus, by flattery, music penetrates into our hearts, for it presents the image of the complete satisfaction of its wishes. More closely considered, we see in this procedure of melody a condition which, to a certain extent, is inward (the harmonious) meet with an outward condition (the rhythmical), as if by an accident, — which is certainly brought about by the composer, and which may, so far, be compared to rhyme in poetry. But this is just the copy of the meeting of our wishes with the favourable outward circumstances which are independent of them, and is thus the picture of happiness. The effect of the suspension also deserves to be considered here. It is a dissonance which delays the final consonance, which is awaited with certainty; and thus the

longing for it is strengthened, and its appearance satisfies all the more. Clearly an analogue of the heightened satisfaction of the will through delay. The complete cadence requires the preceding chord of the seventh on the dominant; because the most deeply felt satisfaction and the most entire relief can only follow the most earnest longing. Thus, in general, music consists of a constant succession of more or less disquieting chords, *i.e.*, chords which excite longing, and more or less quieting and satisfying chords; just as the life of the heart (the will) is a constant succession of greater or less disquietude through desire and aversion, and just as various degrees of relief. Accordingly the harmonious sequence of chords consists of the correct alternation of dissonance and consonance. A succession of merely consonant chords would be satiating, wearisome, and empty, like the languor produced by the satisfaction of all wishes. Therefore dissonances must be introduced, although they disquiet us and affect us almost painfully, but only in order to be resolved again in consonances with proper preparation. Indeed, in the whole of music there are really only two fundamental chords, the dissonant chord of the seventh and the consonant triad, to which all chords that occur can be referred. This just corresponds to the fact, that for the will there are at bottom only dissatisfaction and satisfaction, under however many forms they may present themselves. And as there are two general fundamental moods of the mind, serenity, or at least healthiness, and sadness, or even oppression, so music has two general keys, the major and the minor, which correspond to these, and it must always be in one of the two. But it is, in fact, very wonderful that there is a sign of pain which is neither physically painful nor yet conventional, but which nevertheless is suitable and unmistakable: the minor. From this we may measure how deeply music is founded in the nature of things and of man. With northern nations, whose life is subject to hard conditions, especially with the Russians, the minor prevails, even in the church music. Allegro in the minor is very common in French music, and is characteristic of it; it is as if one danced while one's shoe pinched.

I add further a few subsidiary remarks. When the key-note is changed, and with it the value of all the intervals, in consequence of which the same note figures as the second, the third, the fourth, and so on, the notes of the scale are analogous to actors, who must assume now one rôle, now another, while their person remains the same. That the actors are often not precisely suited to these rôles may be compared to the unavoidable impurity of every

harmonic system (referred to at the end of § 52 of the first volume) which the equal temperament has introduced.

Perhaps some may be offended, that, according to this metaphysic of it, music, which so often exalts our minds, which seems to us to speak of other and better worlds than ours, yet really only flatters the will to live, because it exhibits to it its nature, deludes it with the image of its success, and at the end expresses its satisfaction and contentment. The following passage from the "*Vedas*" may serve to quiet such doubts: "Etanand sroup, quod forma gaudii est, τον pram Atma ex hoc dicunt, quod quocunque loco gaudium est, particula e gaudio ejus est" (*Oupnekhat*, vol. i. p. 405; *et iterum*, vol. ii. p. 215).

Supplements to the Fourth Book.

"Tous les hommes désirent uniquement de se délivrer de la mort: ils ne savent pas se délivrer de la vie."

— *Lao-tsen-Tao-te-King*, ed. Stan. Julien, p. 184.

Chapter XL. Preface.

The supplements to this fourth book would be very considerable if it were not that two of its principal subjects which stand specially in need of being supplemented — the freedom of the will and the foundation of ethics — have, on the occasion of prize questions being set by two Scandinavian Academies, been fully worked out by me in the form of a monograph, which was laid before the public in the year 1841 under the title, "The Two Fundamental Problems of Ethics." Accordingly I assume an acquaintance on the part of my readers with the work which has just been mentioned, just as unconditionally as in the supplements to the second book I have assumed it with regard to the work "On the Will in Nature." In general I make the demand that whoever wishes to make himself acquainted with my philosophy shall read every line of me. For I am no voluminous writer, no fabricator of compendiums, no earner of pecuniary rewards, not one whose writings aim at the approbation of a minister; in a word, not one whose pen is under the influence of personal ends. I strive after nothing but the truth, and write as the ancients wrote, with the sole intention of preserving my thoughts, so that they may be for the benefit of those who understand how to meditate upon them and prize them. Therefore I have written little, but that little with reflection and at long intervals, and accordingly I have also confined within the smallest possible limits those repetitions which in philosophical works are sometimes unavoidable on account of the connection, and from which no single philosopher is free; so that by far the most of what I have to say is only to be found in one place. On this account, then, whoever wishes to learn from me and understand me must leave nothing unread that I have written. Yet one can judge me and criticise me without this, as experience has shown; and to this also I further wish much pleasure.

Meanwhile the space gained by the said elimination of two important subjects will be very welcome to us. For since those explanations, which every man has more at heart than anything else, and which therefore in every system, as ultimate results, form the apex of its pyramid, are also crowded together in my last book, a larger space will gladly be granted to every firmer proof or more accurate account of these. Besides this we have been able to discuss here, as belonging to the doctrine of the "assertion of

the will to live," a question which in our fourth book itself remained untouched, as it was also entirely neglected by all philosophers before me: it is the inner significance and real nature of the sexual love, which sometimes rises to a vehement passion — a subject which it would not have been paradoxical to take up in the ethical part of philosophy if its importance had been known.

Chapter XLI.[27] On Death And Its Relation To The Indestructibility Of Our True Nature.

Death is the true inspiring genius, or the muse of philosophy, wherefore Socrates has defined the latter as θανατου μελετη. Indeed without death men would scarcely philosophise. Therefore it will be quite in order that a special consideration of this should have its place here at the beginning of the last, most serious, and most important of our books.

The brute lives without a proper knowledge of death; therefore the individual brute enjoys directly the absolute imperishableness of the species, for it is only conscious of itself as endless. In the case of men the terrifying certainty of death necessarily entered with reason. But as everywhere in nature with every evil a means of cure, or at least some compensation, is given, the same reflection which introduces the knowledge of death also assists us to metaphysical points of view, which comfort us concerning it, and of which the brute has no need and is incapable. All religious and philosophical systems are principally directed to this end, and are thus primarily the antidote to the certainty of death, which the reflective reason produces out of its own means. Yet the degree in which they attain this end is very different, and certainly one religion or philosophy will, far more than the others, enable men to look death in the face with a quiet glance. Brahmanism and Buddhism, which teach man to regard himself as himself, the original being, the Brahm, to which all coming into being and passing away is essentially foreign, will achieve much more in this respect than such as teach that man is made out of nothing, and actually begins at birth his existence derived from another. Answering to this we find in India a confidence and a contempt for death of which one has no conception in Europe. It is, in fact, a hazardous thing to force upon a man, by early imprinting them, weak and untenable conceptions in this important regard, and thereby making him for ever incapable of taking up correct and stable ones. For example, to teach him that he recently came out of nothing, and consequently through an eternity has been nothing, but yet for the future will be imperishable, is just the same as to teach him that although he is through and through the work of another, yet he will be held responsible through all eternity for his actions. If, then, when the mind ripens and reflection appears, the untenable nature of such doctrines forces itself upon

him, he has nothing better to put in its place, nay, is no longer capable of understanding anything better, and thus loses the comfort which nature had destined for him also, as a compensation for the certainty of death. In consequence of such a process, we see even now in England (1844), among ruined factory hands, the Socialists, and in Germany, among ruined students, the young Hegelians, sink to the absolutely physical point of view, which leads to the result: edite, bibite, post mortem nulla voluptas, and so far may be defined as bestialism.

However, after all that has been taught concerning death, it cannot be denied that, at least in Europe, the opinion of men, nay, often even of the same individual, very frequently vacillates between the conception of death as absolute annihilation and the assumption that we are, as it were, with skin and hair, immortal. Both are equally false: but we have not so much to find a correct mean as rather to gain the higher point of view from which such notions disappear of themselves.

In these considerations I shall first of all start from the purely empirical standpoint. Here there primarily lies before us the undeniable fact that, according to the natural consciousness, man not only fears death for his own person more than anything else, but also weeps violently over the death of those that belong to him, and indeed clearly not egotistically, for his own loss, but out of sympathy for the great misfortune that has befallen them. Therefore he also censures those who in such a case neither weep nor show sadness as hard-hearted and unloving. It is parallel with this that revenge, in its highest degree, seeks the death of the adversary as the greatest evil that can be inflicted. Opinions change with time and place; but the voice of nature remains always and everywhere the same, and is therefore to be heeded before everything else. Now here it seems distinctly to say that death is a great evil. In the language of nature death means annihilation. And that death is a serious matter may be concluded from the fact that, as every one knows, life is no joke. We must indeed deserve nothing better than these two.

In fact, the fear of death is independent of all knowledge; for the brute has it, although it does not know death. Everything that is born brings it with it into the world. But this fear of death is a priori only the reverse side of the will to live, which indeed we all are. Therefore in every brute the fear of its destruction is inborn, like the care for its maintenance. Thus it is the fear of death, and not the mere avoidance of pain, which shows itself in the

anxious carefulness with which the brute seeks to protect itself, and still more its brood, from everything that might become dangerous. Why does the brute flee, trembling, and seek to conceal itself? Because it is simply the will to live, but, as such, is forfeited to death, and wishes to gain time. Such also, by nature, is man. The greatest evil, the worst that can anywhere threaten, is death; the greatest fear is the fear of death. Nothing excites us so irresistibly to the most lively interest as danger to the life of others; nothing is so shocking as an execution. Now the boundless attachment to life which appears here cannot have sprung from knowledge and reflection; to these it rather appears foolish, for the objective worth of life is very uncertain, and at least it remains doubtful whether it is preferable to not being, nay, if experience and reflection come to be expressed, not being must certainly win. If one knocked on the graves, and asked the dead whether they wished to rise again, they would shake their heads. Such is the opinion of Socrates in "Plato's Apology," and even the gay and amiable Voltaire cannot help saying, "On aime la vie; mais le néant ne laisse pas d'avoir du bon;" and again, "Je ne sais pas ce que c'est que la vie éternelle, mais celle-ci est une mauvaise plaisanterie." Besides, life must in any case soon end; so that the few years which perhaps one has yet to be vanish entirely before the endless time when one will be no more. Accordingly it appears to reflection even ludicrous to be so anxious about this span of time, to tremble so much if our own life or that of another is in danger, and to compose tragedies the horror of which has its strength in the fear of death. That powerful attachment to life is therefore irrational and blind; it can only be explained from the fact that our whole inner nature is itself will to live, to which, therefore, life must appear as the highest good, however embittered, short, and uncertain it may always be; and that that will, in itself and originally, is unconscious and blind. Knowledge, on the contrary, far from being the source of that attachment to life, even works against it, for it discloses the worthlessness of life, and thus combats the fear of death. When it conquers, and accordingly the man faces death courageously and composedly, this is honoured as great and noble, thus we hail then the triumph of knowledge over the blind will to live, which is yet the kernel of our own being. In the same way we despise him in whom knowledge is defeated in that conflict, and who therefore clings unconditionally to life, struggles to the utmost against approaching death, and receives it with despair;[28] and yet in him it is only the most original being of ourselves and of nature that expresses itself.

We may here ask, in passing, how could this boundless love of life and endeavour to maintain it in every way as long as possible be regarded as base, contemptible, and by the adherents of every religion as unworthy of this, if it were the gift of good gods, to be recognised with thankfulness? And how could it then seem great and noble to esteem it lightly? Meanwhile, what is confirmed by these considerations is — (1.) that the will to live is the inmost nature of man; (2.) that in itself it is unconscious and blind; (3.) that knowledge is an adventitious principle, which is originally foreign to the will; (4.) that knowledge conflicts with the will, and that our judgment applauds the victory of knowledge over the will.

If what makes death seem so terrible to us were the thought of not being, we would necessarily think with equal horror of the time when as yet we were not. For it is irrefutably certain that not being after death cannot be different from not being before birth, and consequently is also no more deplorable. A whole eternity has run its course while as yet we were not, but that by no means disturbs us. On the other hand, we find it hard, nay, unendurable, that after the momentary intermezzo of an ephemeral existence, a second eternity should follow in which we shall no longer be. Should, then, this thirst for existence have arisen because we have now tasted it and have found it so delightful? As was already briefly explained above, certainly not; far sooner could the experience gained have awakened an infinite longing for the lost paradise of non-existence. To the hope, also, of the immortality of the soul there is always added that of a "better world" — a sign that the present world is not much good. Notwithstanding all this, the question as to our state after death has certainly been discussed, in books and verbally, ten thousand times oftener than the question as to our state before birth. Yet theoretically the one is just as near at hand and as fair a problem as the other; and besides, whoever had answered the one would soon see to the bottom of the other. We have fine declamations about how shocking it would be to think that the mind of man, which embraces the world, and has so many very excellent thoughts, should sink with him into the grave; but we hear nothing about this mind having allowed a whole eternity to pass before it came into being with these its qualities, and how the world must have had to do without it all that time. Yet no question presents itself more naturally to knowledge, uncorrupted by the will, than this: An infinite time has passed before my birth; what was I during this time? Metaphysically, it might perhaps be answered, "I was always I; that

is, all who during that time said I, were just I." But let us look away from this to our present entirely empirical point of view, and assume that I did not exist at all. Then I can console myself as to the infinite time after my death, when I shall not be, with the infinite time when I already was not, as a well-accustomed, and indeed very comfortable, state. For the eternity a parte post without me can be just as little fearful as the eternity a parte ante without me, since the two are distinguished by nothing except by the interposition of an ephemeral dream of life. All proofs, also, for continued existence after death may just as well be applied in partem ante, where they then demonstrate existence before life, in the assumption of which the Hindus and Buddhists therefore show themselves very consistent. Kant's ideality of time alone solves all these riddles. But we are not speaking of that now. This, however, results from what has been said, that to mourn for the time when one will be no more is just as absurd as it would be to mourn over the time when as yet one was not; for it is all the same whether the time which our existence does not fill is related to that which it does fill, as future or as past.

But, also, regarded entirely apart from these temporal considerations, it is in and for itself absurd to look upon not being as an evil; for every evil, as every good, presupposes existence, nay, even consciousness: but the latter ceases with life, as also in sleep and in a swoon; therefore the absence of it is well known to us, and trusted, as containing no evil at all: its entrance, however, is always an affair of a moment. From this point of view Epicurus considered death, and therefore quite rightly said, "ὁ θανατος μηδεν προς ἡμας" (Death does not concern us); with the explanation that when we are death is not, and when death is we are not (*Diog. Laert.*, x. 27). To have lost what cannot be missed is clearly no evil. Therefore ceasing to be ought to disturb us as little as not having been. Accordingly from the standpoint of knowledge there appears absolutely no reason to fear death. But consciousness consists in knowing; therefore, for consciousness death is no evil. Moreover, it is really not this knowing part of our ego that fears death, but the fuga mortis proceeds entirely and alone from the blind will, of which everything living is filled. To this, however, as was already mentioned above, it is essential, just because it is will to live, whose whole nature consists in the effort after life and existence, and which is not originally endowed with knowledge, but only in consequence of its objectification in animal individuals. If now the will, by means of

knowledge, beholds death as the end of the phenomenon with which it has identified itself, and to which, therefore, it sees itself limited, its whole nature struggles against it with all its might. Whether now it has really something to fear from death we will investigate further on, and will then remember the real source of the fear of death, which has been shown here along with the requisite distinction of the willing and the knowing part of our nature.

Corresponding to this, then, what makes death so terrible to us is not so much the end of life — for this can appear to no one specially worthy of regret — but rather the destruction of the organism; really because this is the will itself exhibiting itself as body. But we only really feel this destruction in the evils of disease or of old age; death itself, on the other hand, consists for the subject only in the moment when consciousness vanishes because the activity of the brain ceases. The extension of the stoppage to all the other parts of the organism which follows this is really already an event after death. Thus death, in a subjective regard, concerns the consciousness alone. Now what the vanishing of this may be every one can to a certain extent judge of from going to sleep; but it is still better known to whoever has really fainted, for in this the transition is not so gradual, nor accompanied by dreams, but first the power of sight leaves us, still fully conscious, and then immediately the most profound unconsciousness enters; the sensation that accompanies it, so far as it goes, is anything but disagreeable; and without doubt, as sleep is the brother of death, so the swoon is its twin-brother. Even violent death cannot be painful, for even severe wounds are not felt at all till some time afterwards, often not till the outward signs of them are observed. If they are rapidly mortal, consciousness will vanish before this discovery; if they result in death later, then it is the same as with other illnesses. All those also who have lost consciousness in water, or from charcoal fumes, or through hanging are well known to say that it happened without pain. And now, finally, the death which is properly in accordance with nature, death from old age, euthanasia, is a gradual vanishing and sinking out of existence in an imperceptible manner. Little by little in old age, the passions and desires, with the susceptibility for their objects, are extinguished; the emotions no longer find anything to excite them; for the power of presenting ideas to the mind always becomes weaker, its images fainter; the impressions no longer cleave to us, but pass over without leaving a trace,

the days roll ever faster, events lose their significance, everything grows pale. The old man stricken in years totters about or rests in a corner now only a shadow, a ghost of his former self. What remains there for death to destroy? One day a sleep is his last, and his dreams are —— . They are the dreams which Hamlet inquires after in the famous soliloquy. I believe we dream them even now.

I have here also to remark that the maintenance of the life process, although it has a metaphysical basis, does not go on without resistance, and consequently not without effort. It is this to which the organism yields every night, on account of which it then suspends the brain function and diminishes certain secretions, the respiration, the pulse, and the development of heat. From this we may conclude that the entire ceasing of the life process must be a wonderful relief to its motive force; perhaps this has some share in the expression of sweet contentment on the faces of most dead persons. In general the moment of death may be like the moment of awaking from a heavy dream that has oppressed us like a nightmare.

Up to this point the result we have arrived at is that death, however much it may be feared, can yet really be no evil. But often it even appears as a good thing, as something wished for, as a friend. All that have met with insuperable obstacles to their existence or their efforts, that suffer from incurable diseases or inconsolable griefs, have as a last refuge, which generally opens to them of its own accord, the return into the womb of nature, from which they arose for a short time, enticed by the hope of more favourable conditions of existence than have fallen to their lot, and the same path out of which constantly remains open. That return is the cessio bonorum of life. Yet even here it is only entered upon after a physical and moral conflict: so hard does one struggle against returning to the place from which one came out so lightly and readily, to an existence which has so much suffering and so little pleasure to offer. The Hindus give the god of death, Yama, two faces; one very fearful and terrible, and one very cheerful and benevolent. This partly explains itself from the reflections we have just made.

At the empirical point of view at which we still stand, the following consideration is one which presents itself of its own accord, and therefore deserves to be accurately defined by illustration, and thereby referred to its proper limits. The sight of a dead body shows me that sensibility, irritability, circulation of the blood, reproduction, &c., have here ceased. I

conclude from this with certainty that what actuated these hitherto, which was yet always something unknown to me, now actuates them no longer, thus has departed from them. But if I should now wish to add that this must have been just what I have known only as consciousness, consequently as intelligence (soul), this would be not only an unjustified but clearly a false conclusion. For consciousness has always showed itself to me not as the cause, but as the product and result of the organised life, for it rose and sank in consequence of this in the different periods of life, in health and sickness, in sleep, in a swoon, in awaking, &c., thus always appeared as effect, never as cause of the organised life, always showed itself as something which arises and passes away, and again arises, so long as the conditions of this still exist, but not apart from them. Nay, I may also have seen that the complete derangement of consciousness, madness, far from dragging down with it and depressing the other forces, or indeed endangering life, heightens these very much, especially irritability or muscular force, and rather lengthens than shortens life, if other causes do not come in. Then, also: I knew individuality as a quality of everything organised, and therefore, if this is a self-conscious organism, also of consciousness. But there exists no occasion now to conclude that individuality was inherent in that vanished principle, which imparts life, and is completely unknown to me; all the less so as I see that everywhere in nature each particular phenomenon is the work of a general force which is active in thousands of similar phenomena. But, on the other hand, there is just as little occasion to conclude that because the organised life has ceased here that force which hitherto actuated it has also become nothing; as little as to infer the death of the spinner from the stopping of the spinning-wheel. If a pendulum, by finding its centre of gravity, at last comes to rest, and thus its individual apparent life has ceased, no one will imagine that gravitation is now annihilated; but every one comprehends that, after as before, it is active in innumerable phenomena. Certainly it might be urged against this comparison, that here also, in this pendulum, gravitation has not ceased to be active, but only to manifest its activity palpably; whoever insists on this may think, instead, of an electrical body, in which, after its discharge, electricity has actually ceased to be active. I only wished to show in this that we ourselves recognise in the lowest forces of nature an eternity and ubiquity with regard to which the transitory nature of their fleeting phenomena never makes us err for a moment. So much the less, then,

should it come into our mind to regard the ceasing of life as the annihilation of the living principle, and consequently death as the entire destruction of the man. Because the strong arm which, three thousand years ago, bent the bow of Ulysses is no more, no reflective and well-regulated understanding will regard the force which acted so energetically in it as entirely annihilated, and therefore, upon further reflection, will also not assume that the force which bends the bow to-day first began with this arm. The thought lies far nearer us, that the force which earlier actuated the life which now has vanished is the same which is active in the life which now flourishes: nay, this is almost inevitable. Certainly, however, we know that, as was explained in the second book, only that is perishable which is involved in the causal series; but only the states and forms are so involved. On the other hand, untouched by the change of these which is introduced by causes, there remain on the one side matter, and on the other side natural forces: for both are the presupposition of all these changes. But the principle of our life we must, primarily at least, conceive as a force of nature, until perhaps a more profound investigation has brought us to know what it is in itself. Thus, taken simply as a force of nature, the vital force remains entirely undisturbed by the change of forms and states, which the bond of cause and effect introduces and carries off again, and which alone are subject to the process of coming into being and passing away, as it lies before us in experience. Thus so far the imperishable nature of our true being can be proved with certainty. But it is true this will not satisfy the claims which are wont to be made upon proofs of our continued existence after death, nor insure the consolation which is expected from such proofs. However, it is always something; and whoever fears death as an absolute annihilation cannot afford to despise the perfect certainty that the inmost principle of his life remains untouched by it. Nay, the paradox might be set up, that that second thing also which, just like the forces of nature, remains untouched by the continual change under the guidance of causality, thus matter, by its absolute permanence, insures us indestructibility, by virtue of which whoever was incapable of comprehending any other might yet confidently trust in a certain imperishableness. "What!" it will be said, "the permanence of the mere dust, of the crude matter, is to be regarded as a continuance of our being?" Oh! do you know this dust, then? Do you know what it is and what it can do? Learn to know it before you despise it. This matter which now lies there as dust and ashes will soon, dissolved in water,

form itself as a crystal, will shine as metal, will then emit electric sparks, will by means of its galvanic intensity manifest a force which, decomposing the closest combinations, reduces earths to metals; nay, it will, of its own accord, form itself into plants and animals, and from its mysterious womb develop that life for the loss of which you, in your narrowness, are so painfully anxious. Is it, then, absolutely nothing to continue to exist as such matter? Nay, I seriously assert that even this permanence of matter affords evidence of the indestructibility of our true nature, though only as in an image or simile, or, rather, only as in outline. To see this we only need to call to mind the explanation of matter given in chapter 24, from which it resulted that mere formless matter — this basis of the world of experience which is never perceived for itself alone, but assumed as constantly remaining — is the immediate reflection, the visibility in general, of the thing in itself, thus of the will. Therefore, whatever absolutely pertains to the will as such holds good also of matter, and it reflects the true eternal nature of the will under the image of temporal imperishableness. Because, as has been said, nature does not lie, no view which has sprung from a purely objective comprehension of it, and been logically thought out, can be absolutely false, but at the most only very one-sided and imperfect. Such, however, is, indisputably, consistent materialism; for instance, that of Epicurus, just as well as the absolute idealism opposed to it, like that of Berkeley, and in general every philosophical point of view which has proceeded from a correct apperçu, and been honestly carried out. Only they are all exceedingly one-sided comprehensions, and therefore, in spite of their opposition, they are all true, each from a definite point of view; but as soon as one has risen above this point of view, then they only appear as relatively and conditionally true. The highest standpoint alone, from which one surveys them all and knows them in their relative truth, but also beyond this, in their falseness, can be that of absolute truth so far as this is in general attainable. Accordingly we see, as was shown above, that in the very crude, and therefore very old, point of view of materialism proper the indestructibility of our true nature in itself is represented, as by a mere shadow of it, the imperishableness of matter; as in the already higher naturalism of an absolute physics it is represented by the ubiquity and eternity of the natural forces, among which the vital force is at least to be counted. Thus even these crude points of view contain the assertion that the

living being suffers no absolute annihilation through death, but continues to exist in and with the whole of nature.

The considerations which have brought us to this point, and to which the further explanations link themselves on, started from the remarkable fear of death which fills all living beings. But now we will change the standpoint and consider how, in contrast to the individual beings, the whole of nature bears itself with reference to death. In doing this, however, we still always remain upon the ground of experience.

Certainly we know no higher game of chance than that for death and life. Every decision about this we watch with the utmost excitement, interest, and fear; for in our eyes all in all is at stake. On the other hand, nature, which never lies, but is always straightforward and open, speaks quite differently upon this theme, speaks like Krishna in the Bhagavadgita. What it says is: The death or the life of the individual is of no significance. It expresses this by the fact that it exposes the life of every brute, and even of man, to the most insignificant accidents without coming to the rescue. Consider the insect on your path; a slight, unconscious turning of your step is decisive as to its life or death. Look at the wood-snail, without any means of flight, of defence, of deception, of concealment, a ready prey for all. Look at the fish carelessly playing in the still open net; the frog restrained by its laziness from the flight which might save it; the bird that does not know of the falcon that soars above it; the sheep which the wolf eyes and examines from the thicket. All these, provided with little foresight, go about guilelessly among the dangers that threaten their existence every moment. Since now nature exposes its organisms, constructed with such inimitable skill, not only to the predatory instincts of the stronger, but also to the blindest chance, to the humour of every fool, the mischievousness of every child without reserve, it declares that the annihilation of these individuals is indifferent to it, does it no harm, has no significance, and that in these cases the effect is of no more importance than the cause. It says this very distinctly, and it does not lie; only it makes no comments on its utterances, but rather expresses them in the laconic style of an oracle. If now the all-mother sends forth her children without protection to a thousand threatening dangers, this can only be because she knows that if they fall they fall back into her womb, where they are safe; therefore their fall is a mere jest. Nature does not act otherwise with man than with the brutes. Therefore its declaration extends also to man: the life and death of the individual are

indifferent to it. Accordingly, in a certain sense, they ought also to be indifferent to us, for we ourselves are indeed nature. Certainly, if only we saw deep enough, we would agree with nature, and regard life and death as indifferently as it does. Meanwhile, by means of reflection, we must attribute that carelessness and indifference of nature towards the life of the individuals to the fact that the destruction of such a phenomenon does not in the least affect its true and proper nature.

If we further ponder the fact, that not only, as we have just seen, are life and death dependent upon the most trifling accidents, but that the existence of the organised being in general is an ephemeral one, that animal and plant arise to-day and pass away to-morrow, and birth and death follow in quick succession, while to the unorganised things which stand so much lower an incomparably longer duration is assured, and an infinite duration to the absolutely formless matter alone, to which, indeed, we attribute this a priori, — then, I think, the thought must follow of its own accord, even from the purely empirical, but objective and unprejudiced comprehension of such an order of things, that this is only a superficial phenomenon, that such a constant arising and passing away can by no means touch the root of things, but can only be relative, nay, only apparent, in which the true inner nature of that thing is not included, the nature which everywhere evades our glance and is thoroughly mysterious, but rather that this continues to exist undisturbed by it; although we can neither apprehend nor conceive the manner in which this happens, and must therefore think of it only generally as a kind of tour de passe-passe which took place there. For that, while what is most imperfect, the lowest, the unorganised, continues to exist unassailed, it is just the most perfect beings, the living creatures, with their infinitely complicated and inconceivably ingenious organisations, which constantly arise, new from the very foundation, and after a brief span of time absolutely pass into nothingness, to make room for other new ones like them coming into existence out of nothing — this is something so obviously absurd that it can never be the true order of things, but rather a mere veil which conceals this, or, more accurately, a phenomenon conditioned by the nature of our intellect. Nay, the whole being and not being itself of these individuals, in relation to which death and life are opposites, can only be relative. Thus the language of nature, in which it is given us as absolute, cannot be the true and ultimate expression of the nature of things and of the order of the world, but indeed only a patois du pays, *i.e.*, something merely

relatively true, — something to be understood cum grano salis, or, to speak properly, something conditioned by our intellect; I say, an immediate, intuitive conviction of the kind which I have tried to describe in words will press itself upon every one; *i.e.*, certainly only upon every one whose mind is not of an utterly ordinary species, which is absolutely only capable of knowing the particular simply and solely as such, which is strictly limited to the knowledge of individuals, after the manner of the intellect of the brutes. Whoever, on the other hand, by means of a capacity of an only somewhat higher power, even just begins to see in the individual beings their universal, their Ideas, will also, to a certain extent, participate in that conviction, and that indeed as an immediate, and therefore certain, conviction. In fact, it is also only small, limited minds that fear death quite seriously as their annihilation, and persons of decidedly superior capacity are completely free from such terrors. Plato rightly bases the whole of philosophy upon the knowledge of the doctrine of Ideas, *i.e.*, upon the perception of the universal in the particular. But the conviction here described, which proceeds directly from the comprehension of nature, must have been exceedingly vivid in those sublime authors of the Upanishads of the Vedas, who can scarcely be thought of as mere men, for it speaks to us so forcibly out of an innumerable number of their utterances that we must ascribe this immediate illumination of their mind to the fact that these wise men, standing nearer the origin of our race in time, comprehended the nature of things more clearly and profoundly than the already deteriorated race, ὁιοι νυν βροτοι εισιν, is able to do. But certainly their comprehension is assisted by the natural world of India, which is endowed with life in a very different degree from our northern world. However, thorough reflection, as pursued by Kant's great mind, leads by another path to the same result, for it teaches us that our intellect, in which that phenomenal world which changes so fast exhibits itself, does not comprehend the true ultimate nature of things, but merely its phenomenal manifestation, and indeed, as I add, because it is originally only destined to present the motives to our will, *i.e.*, to be serviceable to it in the pursuit of its paltry ends.

Let us, however, carry our objective and unprejudiced consideration of nature still further. If I kill a living creature, whether a dog, a bird, a frog, or even only an insect, it is really inconceivable that this being, or rather the original force by virtue of which such a marvellous phenomenon exhibited itself just the moment before, in its full energy and love of life, should have

been annihilated by my wicked or thoughtless act. And again, on the other hand, the millions of animals of every kind which come into existence every moment, in infinite variety, full of force and activity, can never, before the act of their generation, have been nothing at all, and have attained from nothing to an absolute beginning. If now in this way I see one of these withdraw itself from my sight, without me knowing where it goes, and another appear without me knowing whence it comes; if, moreover, both have the same form, the same nature, the same character, and only not the same matter, which yet during their existence they continually throw off and renew; then certainly the assumption, that that which vanishes and that which appears in its place are one and the same, which has only experienced a slight alteration, a renewal of the form of its existence, and that consequently death is for the species what sleep is for the individual; this assumption, I say, lies so close at hand that it is impossible not to light upon it, unless the mind, perverted in early youth by the imprinting of false views, hurries it out of the way, even from a distance, with superstitious fear. But the opposite assumption that the birth of an animal is an arising out of nothing, and accordingly that its death is its absolute annihilation, and this with the further addition that man, who has also originated out of nothing, has yet an individual, endless existence, and indeed a conscious existence, while the dog, the ape, the elephant, are annihilated by death, is really something against which the healthy mind revolts and which it must regard as absurd. If, as is sufficiently often repeated, the comparison of the results of a system with the utterances of the healthy mind is supposed to be a touchstone of its truth, I wish the adherents of the system which was handed down from Descartes to the pre-Kantian eclectics, nay, which even now is still the prevailing view of the great majority of cultured people in Europe, would apply this touchstone here.

Throughout and everywhere the true symbol of nature is the circle, because it is the schema or type of recurrence. This is, in fact, the most universal form in nature, which it carries out in everything, from the course of the stars down to the death and the genesis of organised beings, and by which alone, in the ceaseless stream of time, and its content, a permanent existence, *i.e.*, a nature, becomes possible.

If in autumn we consider the little world of insects, and see how one prepares its bed to sleep the long, rigid winter-sleep; another spins its cocoon to pass the winter as a chrysalis, and awake in spring rejuvenated

and perfected; and, finally, how most of them, intending themselves to rest in the arms of death, merely arrange with care the suitable place for their egg, in order to issue forth again from it some day renewed; — this is nature's great doctrine of immortality, which seeks to teach us that there is no radical difference between sleep and death, but the one endangers existence just as little as the other. The care with which the insect prepares a cell, or hole, or nest, deposits its egg in it, together with food for the larva that will come out of it in the following spring, and then quietly dies, is just like the care with which in the evening a man lays ready his clothes and his breakfast for the next morning, and then quietly goes to sleep; and at bottom it could not take place at all if it were not that the insect which dies in autumn is in itself, and according to its true nature, just as much identical with the one which is hatched out in the spring as the man who lies down to sleep is identical with the man who rises from it.

If now, after these considerations, we return to ourselves and our own species, then cast our glance forward far into the future, and seek to present to our minds the future generations, with the millions of their individuals in the strange form of their customs and pursuits, and then interpose with the question: Whence will all these come? Where are they now? Where is the fertile womb of that nothing, pregnant with worlds, which still conceals the coming races? Would not the smiling and true answer to this be, Where else should they be than there where alone the real always was and will be, in the present and its content? — thus with thee, the foolish questioner, who in this mistaking of his own nature is like the leaf upon the tree, which, fading in autumn and about to fall, complains at its destruction, and will not be consoled by looking forward to the fresh green which will clothe the tree in spring, but says lamenting, "I am not these! These are quite different leaves!" Oh, foolish leaf! Whither wilt thou? And whence should others come? Where is the nothing whose abyss thou fearest? Know thine own nature, that which is so filled with thirst for existence; recognise it in the inner, mysterious, germinating force of the tree, which, constantly one and the same in all generations of leaves, remains untouched by all arising and passing away. And now, οἱη περ φυλλων γενεη, τοιηδε και ανδρων (Qualis foliorum generatio, talis et hominum). Whether the fly which now buzzes round me goes to sleep in the evening, and buzzes again tomorrow, or dies in the evening, and in spring another fly buzzes which has sprung from its egg: that is in itself the same thing; but therefore the knowledge which

exhibits this as two fundamentally different things is not unconditioned, but relative, a knowledge of the phenomenon, not of the thing in itself. In the morning the fly exists again; it also exists again in the spring. What distinguishes for it the winter from the night? In Burdach's "Physiology," vol. i. § 275, we read, "Till ten o'clock in the morning no Cercaria ephemera (one of the infusoria) is to be seen (in the infusion), and at twelve the whole water swarms with them. In the evening they die, and the next morning they again appear anew." So it was observed by Nitzsch six days running.

So everything lingers but a moment, and hastens on to death. The plant and the insect die at the end of the summer, the brute and the man after a few years: death reaps unweariedly. Yet notwithstanding this, nay, as if this were not so at all, everything is always there and in its place, just as if everything were imperishable. The plant always thrives and blooms, the insect hums, the brute and the man exist in unwasted youth, and the cherries that have already been enjoyed a thousand times we have again before us every summer. The nations also exist as immortal individuals, although sometimes their names change; even their action, what they do and suffer, is always the same; although history always pretends to relate something different: for it is like the kaleidoscope, which at every turn shows a new figure, while we really always have the same thing before our eyes. What then presses itself more irresistibly upon us than the thought that that arising and passing away does not concern the real nature of things, but this remains untouched by it, thus is imperishable, and therefore all and each that wills to exist actually exists continuously and without end. Accordingly at every given point of time all species of animals, from the gnat to the elephant, exist together complete. They have already renewed themselves many thousand times, and withal have remained the same. They know nothing of others like them, who have lived before them, or will live after them; it is the species which always lives, and in the consciousness of the imperishable nature of the species and their identity with it the individuals cheerfully exist. The will to live manifests itself in an endless present, because this is the form of the life of the species, which, therefore, never grows old, but remains always young. Death is for it what sleep is for the individual, or what winking is for the eye, by the absence of which the Indian gods are known, if they appear in human form. As through the entrance of night the world vanishes, but yet does not for a moment cease to

exist, so man and brute apparently pass away through death, and yet their true nature continues, just as undisturbed by it. Let us now think of that alternation of death and birth as infinitely rapid vibrations, and we have before us the enduring objectification of the will, the permanent Ideas of being, fixed like the rainbow on the waterfall. This is temporal immortality. In consequence of this, notwithstanding thousands of years of death and decay, nothing has been lost, not an atom of the matter, still less anything of the inner being, that exhibits itself as nature. Therefore every moment we can cheerfully cry, "In spite of time, death, and decay, we are still all together!"

Perhaps we would have to except whoever had once said from the bottom of his heart, with regard to this game, "I want no more." But this is not yet the place to speak of this.

But we have certainly to draw attention to the fact that the pain of birth and the bitterness of death are the two constant conditions under which the will to live maintains itself in its objectification, *i.e.*, our inner nature, untouched by the course of time and the death of races, exists in an everlasting present, and enjoys the fruit of the assertion of the will to live. This is analogous to the fact that we can only be awake during the day on condition that we sleep during the night; indeed the latter is the commentary which nature offers us for the understanding of that difficult passage.[29]

For the substratum, or the content, πληρωμα, or the material of the present, is through all time really the same. The impossibility of knowing this identity directly is just time, a form and limitation of our intellect. That on account of it, for example, the future event is not yet, depends upon an illusion of which we become conscious when that event has come. That the essential form of our intellect introduces such an illusion explains and justifies itself from the fact that the intellect has come forth from the hands of nature by no means for the apprehension of the nature of things, but merely for the apprehension of motives, thus for the service of an individual and temporal phenomenon of will.[30]

Whoever comprehends the reflections which here occupy us will also understand the true meaning of the paradoxical doctrine of the Eleatics, that there is no arising and passing away, but the whole remains immovable: "Παρμενιδης και Μελισσος ανῃρουν γενεσιν και φθοραν, δια το νομιξειν το παν ακινητον" (Parmenides et Melissus ortum et interitum tollebant,

quoniam nihil moveri putabant), *Stob. Ecl.*, i. 21. Light is also thrown here upon the beautiful passage of Empedocles which Plutarch has preserved for us in the book, "*Adversus Coloten*," c. 12: —

"Νηπιοι; ου γαρ σφιν δολιχοφρονες εισι μεριμναι,
Οἱ δη γινεσθαι παρος ουκ εον ελπιζουσι,
Η τι καταθνησκειν και εξολλυσθαι ἁπαντη.
Ουκ αν ανηρ τοιαυτα σοφος φρεσι μαντευσαιτο,
Ὡς οφρα μεν τε βιωσι (το δη βιοτον καλεουσι),
Τοφρα μεν ουν εισιν, και σφιν παρα δεινα και ἑσθλα
Πριν τε παγεν τε βροτοι, και επει λυθεν, ουδεν αρ᾽ ἑισιν."
(Stulta, et prolixas non admittentia curas
Pectora: qui sperant, existere posse, quod ante
Non fuit, aut ullam rem pessum protinus ire; —
Non animo prudens homo quod præsentiat ullus,
Dum vivunt (namque hoc vitaï nomine signant),
Sunt, et fortuna tum conflictantur utraque:
Ante ortum nihil est homo, nec post funera quidquam.)

The very remarkable and, in its place, astonishing passage in Diderot's "*Jacques le fataliste*," deserves not less to be mentioned here: "Un château immense, au frontispice duquel on lisait: *‹ Je n'appartiens à personne, et j'appartiens à tout le monde: vous y étiez avant que d'y entrer, vous y serez encore, quand vous en sortirez ›*."

Certainly in the sense in which, when he is begotten, the man arises out of nothing, he becomes nothing through death. But really to learn to know this "nothing" would be very interesting; for it only requires moderate acuteness to see that this empirical nothing is by no means absolute, *i.e.*, such as would in every sense be nothing. We are already led to this insight by the observation that all qualities of the parents recur in the children, thus have overcome death. Of this, however, I will speak in a special chapter.

There is no greater contrast than that between the ceaseless flight of time, which carries its whole content with it, and the rigid immobility of what is actually present, which at all times is one and the same. And if from this point of view we watch in a purely objective manner the immediate events of life, the Nunc stans becomes clear and visible to us in the centre of the wheel of time. To the eye of a being of incomparably longer life, which at one glance comprehended the human race in its whole duration,

the constant alternation of birth and death would present itself as a continuous vibration, and accordingly it would not occur to it at all to see in this an ever new arising out of nothing and passing into nothing; but just as to our sight the quickly revolving spark appears as a continuous circle, the rapidly vibrating spring as a permanent triangle, the vibrating cord as a spindle, so to this eye the species would appear as that which has being and permanence, death and life as vibrations.

We will have false conceptions of the indestructibility of our true nature by death, so long as we do not make up our minds to study it primarily in the brutes, but claim for ourselves alone a class apart from them, under the boastful name of immortality. But it is this pretension alone, and the narrowness of view from which it proceeds, on account of which most men struggle so obstinately against the recognition of the obvious truth that we are essentially, and in the chief respect, the same as the brutes; nay, that they recoil at every hint of our relationship with these. But it is this denial of the truth which more than anything else closes against them the path to real knowledge of the indestructibility of our nature. For if we seek anything upon a wrong path, we have just on that account forsaken the right path, and upon the path we follow we will never attain to anything in the end but late disillusion. Up, then, follow the truth, not according to preconceived notions, but as nature leads! First of all, learn to recognise in the aspect of every young animal the existence of the species that never grows old, which, as a reflection of its eternal youth, imparts to every individual a temporary youth, and lets it come forth as new and fresh as if the world were of to-day. Let one ask himself honestly whether the swallow of this year’s spring is absolutely a different one from the swallow of the first spring, and whether really between the two the miracle of the creation out of nothing has repeated itself millions of times, in order to work just as often into the hands of absolute annihilation. I know well that if I seriously assured any one that the cat which now plays in the yard is still the same one which made the same springs and played the same tricks there three hundred years ago, he would think I was mad; but I also know that it is much madder to believe that the cat of to-day is through and through and in its whole nature quite a different one from the cat of three hundred years ago. One only requires truly and seriously to sink oneself in the contemplation of one of these higher vertebrates in order to become distinctly conscious that this unfathomable nature, taken as a whole, as it

exists there, cannot possibly become nothing; and yet, on the other hand, one knows its transitoriness. This depends upon the fact that in this animal the infinite nature of its Idea (species) is imprinted in the finiteness of the individual. For in a certain sense it is of course true that in the individual we always have before us another being — in the sense which depends upon the principle of sufficient reason, in which are also included time and space, which constitute the principium individuationis. But in another sense it is not true — in the sense in which reality belongs to the permanent forms of things, the Ideas alone, and which was so clearly evident to Plato that it became his fundamental thought, the centre of his philosophy; and he made the comprehension of it the criterion of capacity for philosophising in general.

As the scattered drops of the roaring waterfall change with lightning rapidity, while the rainbow, whose supporter they are, remains immovably at rest, quite untouched by that ceaseless change, so every Idea, *i.e.*, every species of living creature remains quite untouched by the continual change of its individuals. But it is the Idea, or the species in which the will to live is really rooted, and manifests itself; and therefore also the will is only truly concerned in the continuance of the species. For example, the lions which are born and die are like the drops of the waterfall; but the leonitas, the Idea or form of the lion, is like the unshaken rainbow upon it. Therefore Plato attributed true being to the Ideas alone, *i.e.*, to the species; to the individuals only a ceaseless arising and passing away. From the profound consciousness of his imperishable nature really springs also the confidence and peace of mind with which every brute, and even human individual, moves unconcernedly along amid a host of chances, which may annihilate it any moment, and, moreover, moves straight on to death: out of its eyes, however, there shines the peace of the species, which that death does not affect, and does not concern. Even to man this peace could not be imparted by uncertain and changing dogmas. But, as was said, the contemplation of every animal teaches that death is no obstacle to the kernel of life, to the will in its manifestation. What an unfathomable mystery lies, then, in every animal! Look at the nearest one; look at your dog, how cheerfully and peacefully he lives! Many thousands of dogs have had to die before it came to this one's turn to live. But the death of these thousands has not affected the Idea of the dog; it has not been in the least disturbed by all that dying. Therefore the dog exists as fresh and endowed with primitive force as if this

were its first day and none could ever be its last; and out of its eyes there shines the indestructible principle in it, the archæus. What, then, has died during those thousands of years? Not the dog — it stands unscathed before us; merely its shadow, its image in our form of knowledge, which is bound to time. Yet how can one even believe that that passes away which for ever and ever exists and fills all time? Certainly the matter can be explained empirically; in proportion as death destroyed the individuals, generation produced new ones. But this empirical explanation is only an apparent explanation: it puts one riddle in the place of the other. The metaphysical understanding of the matter, although not to be got so cheaply, is yet the only true and satisfying one.

Kant, in his subjective procedure, brought to light the truth that time cannot belong to the thing in itself, because it lies pre-formed in our apprehension. Now death is the temporal end of the temporal phenomenon; but as soon as we abstract time, there is no longer any end, and this word has lost all significance. But I, here upon the objective path, am trying to show the positive side of the matter, that the thing in itself remains untouched by time, and by that which is only possible through time, arising and passing away, and that the phenomena in time could not have even that ceaselessly fleeting existence which stands next to nothingness, if there were not in them a kernel of the infinite. Eternity is certainly a conception which has no perception as its foundation; accordingly it has also a merely negative content; it signifies a timeless existence. Time is yet merely an image of eternity, ὀ χρονος εἱκων τον αἱωνος, as Plotinus has it; and in the same way our temporal existence is a mere image of our true nature. This must lie in eternity, just because time is only the form of our knowledge; but on account of this alone do we know our own existence, and that of all things as transitory, finite, and subject to annihilation.

In the second book I have shown that the adequate objectivity of the will as the thing in itself, at each of its grades, is the (Platonic) Idea; similarly in the third book that the Ideas of things have the pure subject of knowledge as their correlative; consequently the knowledge of them only appears exceptionally and temporarily under specially favourable conditions. For individual knowledge, on the other hand, thus in time, the Idea presents itself under the form of the species, which is the Idea broken up through its entrance into time. Therefore the species is the most immediate objectification of the thing in itself, *i.e.*, of the will to live. The inmost

nature of every brute, and also of man, accordingly lies in the species; thus the will to live, which is so powerfully active, is rooted in this, not really in the individual. On the other hand, in the individual alone lies the immediate consciousness: accordingly it imagines itself different from the species, and therefore fears death. The will to live manifests itself in relation to the individual as hunger and the fear of death: in relation to the species as sexual instinct and passionate care for the offspring. In agreement with this we find nature, which is free from that delusion of the individual, as careful for the maintenance of the species as it is indifferent to the destruction of the individuals: the latter are always only means, the former is the end. Therefore a glaring contrast appears between its niggardliness in the endowment of the individuals and its prodigality when the species is concerned. In the latter case from one individual are often annually obtained a hundred thousand germs, and more; for example, from trees, fishes, crabs, termites, and many others. In the former case, on the contrary, only barely enough in the way of powers and organs is given to each to enable it with ceaseless effort to maintain its life. And, therefore, if an animal is injured or weakened it must, as a rule, starve. And where an incidental saving was possible, through the circumstance that one part could upon necessity be dispensed with, it has been withheld, even out of order. Hence, for example, many caterpillars are without eyes; the poor creatures grope in the dark from leaf to leaf, which, since they lack feelers, they do by moving three-fourths of their body back and forward in the air, till they find some object. Hence they often miss their food which is to be found close by. But this happens in consequence of the lex parsimoniæ naturæ, to the expression of which natura nihil facit supervacaneum one may add et nihil largitur. The same tendency of nature shows itself also in the fact that the more fit the individual is, on account of his age, for the propagation of the species, the more powerfully does the vis naturæ medicatrix manifest itself in him, and therefore his wounds heal easily, and he easily recovers from diseases. This diminishes along with the power of generation, and sinks low after it is extinct; for now in the eyes of nature the individual has become worthless.

If now we cast another glance at the scale of existences, with the whole of their accompanying gradations of consciousness, from the polyp up to man, we see this wonderful pyramid, kept in ceaseless oscillation certainly by the constant death of the individuals, yet by means of the bond of generation, enduring in the species through the infinite course of time.

While, then, as was explained above, the objective, the species, presents itself as indestructible, the subjective, which consists merely in the self-consciousness of these beings, seems to be of the shortest duration, and to be unceasingly destroyed, in order, just as often, to come forth again from nothing in an incomprehensible manner. But, indeed, one must be very short-sighted to let oneself be deceived by this appearance, and not to comprehend that, although the form of temporal permanence only belongs to the objective, the subjective, *i.e.*, the will, which lives and manifests itself in all, and with it the subject of the knowledge in which all exhibits itself, must be not less indestructible; because the permanence of the objective, or external, can yet only be the phenomenal appearance of the indestructibility of the subjective or internal; for the former can possess nothing which it has not received on loan from the latter; and cannot be essentially and originally an objective, a phenomenon, and then secondarily and accidentally a subjective, a thing in itself, a self-consciousness. For clearly the former as a manifestation presupposes something which manifests itself, as being for other presupposes a being for self, and as object presupposes a subject; and not conversely: because everywhere the root of things must lie in that which they are for themselves, thus in the subjective, not in the objective, *i.e.*, in that which they are only for others, in a foreign consciousness. Accordingly we found in the first book that the right starting-point for philosophy is essentially and necessarily the subjective, *i.e.*, the idealistic starting-point; and also that the opposite starting-point, that which proceeds from the objective, leads to materialism. At bottom, however, we are far more one with the world than we commonly suppose: its inner nature is our will, its phenomenal appearance is our idea. For any one who could bring this unity of being to distinct consciousness, the difference between the continuance of the external world after his death and his own continuance after death would vanish. The two would present themselves to him as one and the same; nay, he would laugh at the delusion that could separate them. For the understanding of the indestructibility of our nature coincides with that of the identity of the macrocosm and the microcosm. Meanwhile one may obtain light upon what is said here by a peculiar experiment, performed by means of the imagination, an experiment which might be called metaphysical. Let any one try to present vividly to his mind the time, in any case not far distant, when he will be dead. Then he thinks himself away and lets the world go on existing; but soon, to his own astonishment,

he will discover that he was nevertheless still there. For he intended to present the world to his mind without himself; but the ego is the immediate element in consciousness, through which alone the world is brought about, and for which alone it exists. This centre of all existence, this kernel of all reality, is to be abolished, and yet the world is to go on existing; it is a thought which can be conceived in the abstract, but not realised. The endeavour to accomplish this, the attempt to think the secondary without the primary, the conditioned without the condition, that which is supported without the supporter, always fails, much in the same way as the attempt to think an equilateral, right-angled triangle, or a destruction or origination of matter, and similar impossibilities. Instead of what was intended, the feeling here presses upon us that the world is not less in us than we in it, and that the source of all reality lies within us. The result is really this: the time when I shall not be will objectively come; but subjectively it can never come. It might therefore, indeed, be asked, how far every one, in his heart, actually believes in a thing which he really cannot conceive at all; or whether, since the profound consciousness of the indestructibleness of our true nature associates itself with that merely intellectual experiment, which, however, has already been made more or less distinctly by every one, whether, I say, our own death is not perhaps for us at bottom the most incredible thing in the world.

The deep conviction of the indestructibleness of our nature through death, which, as is also shown by the inevitable qualms of conscience at its approach, every one carries at the bottom of his heart, depends altogether upon the consciousness of the original and eternal nature of our being: therefore Spinoza expresses it thus: "Sentimus, experimurque, nos æternos esse." For a reasonable man can only think of himself as imperishable, because he thinks of himself as without beginning, as eternal, in fact as timeless. Whoever, on the other hand, regards himself as having become out of nothing must also think that he will again become nothing; for that an eternity had passed before he was, and then a second eternity had begun, through which he will never cease to be, is a monstrous thought. Really the most solid ground for our immortality is the old principle: "Ex nihilo nihil fit, et in nihilum nihil potest reverti." Theophrastus Paracelsus very happily says (Works, Strasburg, 1603, vol. ii. p. 6): "The soul in me has arisen out of something; therefore it does not come to nothing; for it comes out of something." He gives the true reason. But whoever regards the birth of the

man as his absolute beginning must regard death as his absolute end. For both are what they are in the same sense; consequently every one can only think of himself as immortal so far as he also thinks of himself as unborn, and in the same sense. What birth is, that also is death, according to its nature and significance: it is the same line drawn in two directions. If the former is an actual arising out of nothing, then the latter is also an actual annihilation. But in truth it is only by means of the eternity of our real being that we can conceive it as imperishable, and consequently this imperishableness is not temporal. The assumption that man is made out of nothing leads necessarily to the assumption that death is his absolute end. Thus in this the Old Testament is perfectly consistent; for no doctrine of immortality is suitable to a creation out of nothing. New Testament Christianity has such a doctrine because it is Indian in spirit, and therefore more than probably also of Indian origin, although only indirectly, through Egypt. But to the Jewish stem, upon which that Indian wisdom had to be grafted in the Holy Land, such a doctrine is as little suited as the freedom of the will to its determinism, or as

"Humano capiti cervicem pictor equinam Jungere si velit."

It is always bad if one cannot be thoroughly original, and dare not carve out of the whole wood. Brahmanism and Buddhism, on the other hand, have quite consistently, besides the continued existence after death, an existence before birth to expiate the guilt of which we have this life. Moreover, how distinctly conscious they were of the necessary consistency in this is shown by the following passage from Colebrooke's "History of the Indian Philosophy" in the "Transac. of the Asiatic London Society," vol. i. p. 577: "Against the system of the Bhagavatas which is but partially heretical, the objection upon which the chief stress is laid by Vyaso is, that the soul would not be eternal if it were a production, and consequently had a beginning." Further, in Upham's "Doctrine of Buddhism," p. 110, it is said: "The lot in hell of impious persons called Deitty is the most severe: these are they who, discrediting the evidence of Buddha, adhere to the heretical doctrine that all living beings had their beginning in the mother's womb, and will have their end in death."

Whoever conceives his existence as merely accidental must certainly fear that he will lose it by death. On the other hand, whoever sees, even only in general, that his existence rests upon some kind of original necessity will not believe that this which has produced so wonderful a thing is limited

to such a brief span of time, but that it is active in every one. But he will recognise his existence as necessary who reflects that up till now, when he exists, already an infinite time, thus also an infinity of changes, has run its course, but in spite of this he yet exists; thus the Whole range of all possible states has already exhausted itself without being able to destroy his existence. If he could ever not be, he would already not be now. For the infinity of the time that has already elapsed, with the exhausted possibility of the events in it, guarantees that what exists, exists necessarily. Therefore every one must conceive himself as a necessary being, *i.e.*, as a being whose existence would follow from its true and exhaustive definition if one only had it. In this line of thought, then, really lies the only immanent proof of the imperishableness of our nature, *i.e.*, the only proof of this that holds good within the sphere of empirical data. In this nature existence must inhere, because it shows itself as independent of all states which can possibly be introduced through the chain of causes; for these states have already done what they could, and yet our existence has remained unshaken by it, as the ray of light by the storm wind which it cuts through. If time, of its own resources, could bring us to a happy state, then we would already have been there long ago; for an infinite time lies behind us. But also: if it could lead us to destruction, we would already have long been no more. From the fact that we now exist, it follows, if well considered, that we must at all times exist. For we are ourselves the nature which time has taken up into itself in order to fill its void; consequently it fills the whole of time, present, past, and future, in the same way, and it is just as impossible for us to fall out of existence as to fall out of space. Carefully considered, it is inconceivable that what once exists in all the strength of reality should ever become nothing, and then not be, through an infinite time. Hence has arisen the Christian doctrine of the restoration of all things, that of the Hindus of the constantly repeated creation of the world by Brahma, together with similar dogmas of the Greek philosophers. The great mystery of our being and not being, to explain which these and all kindred dogmas have been devised, ultimately rests upon the fact that the same thing which objectively constitutes an infinite course of time is subjectively an indivisible, ever present present: but who comprehends it? It has been most distinctly set forth by Kant in his immortal doctrine of the ideality of time and the sole reality of the thing in itself. For it results from this that the really essential part of things, of man, of the world, lies permanently and enduringly in the

Nunc stans, firm and immovable; and that the change of the phenomena and events is a mere consequence of our apprehension of them by means of our form of perception, which is time. Accordingly, instead of saying to men, "Ye have arisen through birth, but are immortal," one ought to say to them, "Ye are not nothing," and teach them to understand this in the sense of the saying attributed to Hermes Trismegistus, "Το γαρ όν άει έσται" (Quod enim est, erit semper), _Stob. Ecl._, i. 43, 6. If, however, this does not succeed, but the anxious heart raises its old lament, "I see all beings arise through birth out of nothing, and after a brief term again return to this; my existence also, now in the present, will soon lie in the distant past, and I will be nothing!" — the right answer is, "Dost thou not exist? Hast thou not within thee the valuable present, after which ye children of time so eagerly strive, now within, actually within? And dost thou understand how thou hast attained to it? Knowest thou the paths which have led thee to it, that thou canst know they will be shut against thee by death? An existence of thyself after the destruction of thy body is not conceivable by thee as possible; but can it be more inconceivable to thee than thy present existence, and how thou hast attained to it? Why shouldst thou doubt but that the secret paths to this present, which stood open to thee, will also stand open to every future present?"

If, then, considerations of this kind are at any rate adapted to awaken the conviction that there is something in us which death cannot destroy, this yet only takes place by raising us to a point of view from which birth is not the beginning of our existence. But from this it follows that what is proved to be indestructible by death is not properly the individual, which, moreover, as having arisen through generation, and having in itself the qualities of the father and mother, presents itself as a mere difference of the species, but as such can only be finite. As, in accordance with this, the individual has no recollection of its existence before its birth, so it can have no remembrance of its present existence after death. But every one places his ego in consciousness; this seems to him therefore to be bound to individuality, with which, besides, everything disappears which is peculiar to him, as to this, and distinguishes him from others. His continued existence without individuality becomes to him therefore indistinguishable from the continuance of other beings, and he sees his ego sink. But whoever thus links his existence to the identity of consciousness, and therefore desires an endless existence after death for this, ought to reflect that he can certainly

only attain this at the price of just as endless a past before birth. For since he has no remembrance of an existence before birth, thus his consciousness begins with birth, he must accept his birth as an origination of his existence out of nothing. But then he purchases the endless time of his existence after death for just as long a time before birth; thus the account balances without any profit for him. If, on the other hand, the existence which death leaves untouched is different from that of the individual consciousness, then it must be independent of birth, just as of death; and therefore, with regard to it, it must be equally true to say, "I will always be," and "I have always been;" which then gives two infinities for one. But the great equivocation really lies in the word "I," as any one will see at once who remembers the contents of our second book, and the separation which is made there of the willing from the knowing part of our nature. According as I understand this word I can say, "Death is my complete end;" or, "This my personal phenomenal existence is just as infinitely small a part of my true nature as I am of the world." But the "I" is the dark point in consciousness, as on the retina the exact point at which the nerve of sight enters is blind, as the brain itself is entirely without sensation, the body of the sun is dark, and the eye sees all except itself. Our faculty of knowledge is directed entirely towards without, in accordance with the fact that it is the product of a brain function, which has arisen for the purpose of mere self-maintenance, thus of the search for nourishment and the capture of prey. Therefore every one knows himself only as this individual as it presents itself in external perception. If, on the other hand, he could bring to consciousness what he is besides and beyond this, then he would willingly give up his individuality, smile at the tenacity of his attachment to it, and say, "What is the loss of this individuality to me, who bear in myself the possibility of innumerable individualities?" He would see that even if a continued existence of his individuality does not lie before him, it is yet quite as good as if he had such an existence, because he carries in himself complete compensation for it. Besides, however, it may further be taken into consideration that the individuality of most men is so miserable and worthless that with it they truly lose nothing, and that that in them which may still have some worth is the universal human element; but to this imperishableness can be promised. Indeed, even the rigid unalterableness and essential limitation of every individual would, in the case of an endless duration of it, necessarily at last produce such great weariness by its monotony that only to be relieved of

this one would prefer to become nothing. To desire that the individuality should be immortal really means to wish to perpetuate an error infinitely. For at bottom every individuality is really only a special error, a false step, something that had better not be; nay, something which it is the real end of life to bring us back from. This also finds confirmation in the fact that the great majority, indeed really all men, are so constituted that they could not be happy in whatever kind of world they might be placed. In proportion as such a world excluded want and hardship, they would become a prey to ennui, and in proportion as this was prevented, they would fall into want, misery, and suffering. Thus for a blessed condition of man it would be by no means sufficient that he should be transferred to a "better world," but it would also be necessary that a complete change should take place in himself; that thus he should no longer be what he is, and, on the contrary, should become what he is not. But for this he must first of all cease to be what he is: this desideratum is, as a preliminary, supplied by death, the moral necessity of which can already be seen from this point of view. To be transferred to another world and to have his whole nature changed are, at bottom, one and the same. Upon this also ultimately rests that dependence of the objective upon the subjective which the idealism of our first book shows. Accordingly here lies the point at which the transcendent philosophy links itself on to ethics. If one considers this one will find that the awaking from the dream of life is only possible through the disappearance along with it of its whole ground-warp also, But this is its organ itself, the intellect together with its forms, with which the dream would spin itself out without end, so firmly is it incorporated with it. That which really dreamt this dream is yet different from it, and alone remains over. On the other hand, the fear that with death all will be over may be compared to the case of one who imagines in a dream that there are only dreams without a dreamer. But now, after an individual consciousness has once been ended by death, would it even be desirable that it should be kindled again in order to continue for ever? The greater part of its content, nay, generally its whole content, is nothing but a stream of small, earthly, paltry thoughts and endless cares. Let them, then, at last be stilled! Therefore with a true instinct, the ancients inscribed upon their gravestones: Securitati perpetuæ; — or Bonæ quieti. But if here, as so often has happened, a continued existence of the individual consciousness should be desired, in order to connect with it a future reward or punishment, what would really be aimed at in this would

simply be the compatibility of virtue and egoism. But these two will never embrace: they are fundamentally opposed. On the other hand, the conviction is well founded, which the sight of noble conduct calls forth, that the spirit of love, which enjoins one man to spare his enemy, and another to protect at the risk of his life some one whom he has never seen before, can never pass away and become nothing.

The most thorough answer to the question as to the continued existence of the individual after death lies in Kant's great doctrine of the ideality of time, which just here shows itself specially fruitful and rich in consequences, for it substitutes a purely theoretical but well-proved insight for dogmas which upon one path as upon the other lead to the absurd, and thus settles at once the most exciting of all metaphysical questions. Beginning, ending, and continuing are conceptions which derive their significance simply and solely from time, and are therefore valid only under the presupposition of this. But time has no absolute existence; it is not the manner of being of the thing in itself, but merely the form of our knowledge of our existence and nature, and that of all things, which is just on this account very imperfect, and is limited to mere phenomena. Thus with reference to this knowledge alone do the conceptions of ceasing and continuing find application, not with reference to that which exhibits itself in these, the inner being of things in relation to which these conceptions have therefore no longer any meaning. For this shows itself also in the fact that an answer to the question which arises from those time-conceptions is impossible, and every assertion of such an answer, whether upon one side or the other, is open to convincing objections. One might indeed assert that our true being continues after death because it is false that it is destroyed; but one might just as well assert that it is destroyed because it is false that it continues: at bottom the one is as true as the other. Accordingly something like an antinomy might certainly be set up here. But it would rest upon mere negations. In it one would deny two contradictorily opposite predicates of the subject of the judgment, but only because the whole category of these predicates would be inapplicable to that subject. But if now one denies these two predicates, not together, but separately, it appears as if the contradictory opposite of the predicate which in each case is denied were proved of the subject of the judgment. This, however, depends upon the fact that here incommensurable quantities are compared, for the problem removes us to a scene where time is abolished, and yet asks about temporal

properties which it is consequently equally false to attribute to, or to deny of the subject. This just means: the problem is transcendent. In this sense death remains a mystery.

On the other hand, adhering to that distinction between phenomenon and thing in itself, we can make the assertion that, as phenomenon, man is certainly perishable, but yet his true being will not be involved in this. Thus this true being is indestructible, although, on account of the elimination of time-conceptions which is connected with it, we cannot attribute to it continuance. Accordingly we would be led here to the conception of an indestructibility which would yet be no continuance. Now this is a conception which, having been obtained on the path of abstraction, can certainly also be thought in the abstract, but yet cannot be supported by any perception, and consequently cannot really become distinct; yet, on the other hand, we must here keep in mind that we have not, like Kant, absolutely given up the knowledge of the thing in itself, but know that it is to be sought for in the will. It is true that we have never asserted an absolute and exhaustive knowledge of the thing in itself, but rather have seen very well that it is impossible to know anything as it is absolutely and in itself. For as soon as I know, I have an idea; but this idea, just because it is my idea, cannot be identical with what is known, but repeats it in an entirely different form, for it makes a being for other out of a being for self, and is thus always to be regarded as a phenomenal appearance of the thing in itself. Therefore for a knowing consciousness, however it may be constituted, there can be always only phenomena. This is not entirely obviated even by the fact that it is my own nature which is known; for, since it falls within my knowing consciousness, it is already a reflex of my nature, something different from this itself, thus already in a certain degree phenomenon. So far, then, as I am a knowing being, I have even in my own nature really only a phenomenon; so far, on the other hand, as I am directly this nature itself, I am not a knowing being. For it is sufficiently proved in the second book that knowledge is only a secondary property of our being, and introduced by its animal nature. Strictly speaking, then, we know even our own will always merely as phenomenon, and not as it may be absolutely in and for itself. But in that second book, and also in my work upon the will in nature, it is fully explained and proved that if, in order to penetrate into the inner nature of things, leaving what is given merely indirectly and from without, we stick to the only phenomenon into the nature of which an

immediate insight from within is attainable, we find in this quite definitely, as the ultimate kernel of reality, the will, in which therefore we recognise the thing in itself in so far as it has here no longer space, although it still has time, for its form consequently really only in its most immediate manifestation, and with the reservation that this knowledge of it is still not exhaustive and entirely adequate. Thus in this sense we retain here also the conception of will as that of the thing in itself.

The conception of ceasing to be is certainly applicable to man as a phenomenon in time, and empirical knowledge plainly presents death as the end of this temporal existence. The end of the person is just as real as was its beginning, and in the same sense as before birth we were not, after death we shall be no more. Yet no more can be destroyed by death than was produced by birth; thus not that through which birth first became possible. In this sense natus et denatus is a beautiful expression. But now the whole of empirical knowledge affords us merely phenomena; therefore only phenomena are involved in the temporal processes of coming into being and passing away, and not that which manifests itself in the phenomena, the thing in itself. For this the opposition of coming into being and passing away conditioned by the brain, does not exist at all, but has here lost meaning and significance. It thus remains untouched by the temporal end of a temporal phenomenon, and constantly retains that existence to which the conceptions of beginning, end, and continuance are not applicable. But the thing in itself, so far as we can follow it, is in every phenomenal being the will of this being: so also in man. Consciousness, on the other hand, consists in knowledge. But knowledge, as activity of the brain, and consequently as function of the organism, belongs, as has been sufficiently proved, to the mere phenomenon, and therefore ends with this. The will alone, whose work, or rather whose image was the body, is that which is indestructible. The sharp distinction of will from knowledge, together with the primacy of the former, which constitutes the fundamental characteristic of my philosophy, is therefore the only key to the contradiction which presents itself in so many ways, and arises ever anew in every consciousness, even the most crude, that death is our end, and that yet we must be eternal and indestructible, thus the sentimus, experimurque nos æternos esse of Spinoza. All philosophers have erred in this: they place the metaphysical, the indestructible, the eternal element in man in the intellect. It lies exclusively in the will, which is entirely different from the intellect,

and alone is original. The intellect, as was most fully shown in the second book, is a secondary phenomenon, and conditioned by the brain, therefore beginning and ending with this. The will alone is that which conditions, the kernel of the whole phenomenon, consequently free from the forms of the phenomenon to which time belongs, thus also indestructible. Accordingly with death consciousness is certainly lost, but not that which produced and sustained consciousness; life is extinguished, but not the principle of life also, which manifested itself in it. Therefore a sure feeling informs every one that there is something in him which is absolutely imperishable and indestructible. Indeed the freshness and vividness of memories of the most distant time, of earliest childhood, bears witness to the fact that something in us does not pass away with time, does not grow old, but endures unchanged. But what this imperishable element is one could not make clear to oneself. It is not consciousness any more than it is the body upon which clearly consciousness depends. But it is just that which, when it appears in consciousness, presents itself as will. Beyond this immediate manifestation of it we certainly cannot go; because we cannot go beyond consciousness; therefore the question what that may be when it does not come within consciousness, *i.e.*, what it is absolutely in itself, remains unanswerable.

In the phenomenon, and by means of its forms, time and space, as principium individuationis, what presents itself is that the human individual perishes, while the human race, on the contrary, always remains and lives. But in the true being of things, which is free from these forms, this whole distinction between the individual and the race also disappears, and the two are immediately one. The whole will to live is in the individual, as it is in the race, and therefore the continuance of the species is merely the image of the indestructibility of the individual.

Since, then, the infinitely important understanding of the indestructibility of our true nature by death depends entirely upon the distinction between phenomenon and thing in itself, I wish now to bring this difference into the clearest light by explaining it in the opposite of death, thus in the origin of the animal existence, *i.e.*, generation. For this process, which is just as mysterious as death, presents to us most directly the fundamental opposition between the phenomenal appearance and the true being of things, *i.e.*, between the world as idea and the world as will, and also the entire heterogeneity of the laws of these two. The act of procreation presents itself to us in a twofold manner: first, for self-consciousness, whose only object,

as I have often shown, is the will, with all its affections; and then for the consciousness of other things, *i.e.*, the world of idea, or the empirical reality of things. Now, from the side of the will, thus inwardly, subjectively, for self-consciousness, that act presents itself as the most immediate and complete satisfaction of the will, *i.e.*, as sensual pleasure. From the side of the idea, on the other hand, thus externally, objectively, for the consciousness of other things, this act is just the woof of the most cunning of webs, the foundation of the inexpressibly complicated animal organism, which then only requires to be developed to become visible to our astonished eyes. This organism, whose infinite complication and perfection is only known to him who has studied anatomy, cannot, from the side of the idea, be otherwise conceived and thought of than as a system devised with the most ingenious forethought and carried out with the most consummate skill and exactness, as the most arduous work of profound reflection. But from the side of the will we know, through self-consciousness, the production of this organism as the work of an act which is exactly the opposite of all reflection, an impetuous, blind impulse, an exceedingly pleasurable sensation. This opposition is closely related to the infinite contrast, which is shown above, between the absolute facility with which nature produces its works, together with the correspondingly boundless carelessness with which it abandons them to destruction, and the incalculably ingenious and studied construction of these very works, judging from which they must have been infinitely difficult to make, and their maintenance should have been provided for with all conceivable care; while we have the opposite before our eyes. If now by this certainly very unusual consideration, we have brought together in the boldest manner the two heterogeneous sides of the world, and, as it were, grasped them with one hand, we must now hold them fast in order to convince ourselves of the entire invalidity of the laws of the phenomenon, or the world as idea, for that of will, or the thing in itself. Then it will become more comprehensible to us that while on the side of the idea, that is, in the phenomenal world, there exhibits itself to us now an arising out of nothing, and now an entire annihilation of what has arisen, from that other side, or in itself, a nature lies before us with reference to which the conceptions of arising and passing away have no significance. For, by going back to the root, where, by means of self-consciousness, the phenomenon and the thing in itself meet, we have just, as it were, palpably apprehended that the two are absolutely

incommensurable, and the whole manner of being of the one, together with all the fundamental laws of its being, signify nothing, and less than nothing, in the other. I believe that this last consideration will only be rightly understood by a few, and that it will be displeasing and even offensive to all who do not understand it, but I shall never on this account omit anything that can serve to illustrate my fundamental thought.

At the beginning of this chapter I have explained that the great clinging to life, or rather fear of death, by no means springs from knowledge, in which case it would be the result of the known value of life; but that that fear of death has its root directly in the will, out of the original nature of which it proceeds, in which it is entirely without knowledge, and therefore blind will to live. As we are allured into life by the wholly illusory inclination to sensual pleasure, so we are retained in it by the fear of death, which is certainly just as illusory. Both spring directly from the will, which in itself is unconscious. If, on the contrary, man were merely a knowing being, then death would necessarily be to him not only indifferent, but even welcome. The reflection to which we have here attained now teaches that what is affected by death is merely the knowing consciousness, and the will, on the other hand, because it is the thing in itself, which lies at the foundation of every phenomenon, is free from all that depends upon temporal determinations, thus is also imperishable. Its striving towards existence and manifestation, from which the world results, is constantly satisfied, for this accompanies it as the shadow accompanies the body, for it is merely the visibility of its nature. That yet in us it fears death results from the fact that here knowledge presents its existence to it as merely in the individual phenomenon, whence the illusion arises that it will perish with this, as my image in a mirror seems to be destroyed along with it if the mirror is broken; this then, as contrary to its original nature, which is a blind striving towards existence, fills it with horror. From this now it follows that that in us which alone is capable of fearing death, and also alone fears it, the will, is not affected by it; and that, on the other hand, what is affected by it and really perishes is that which from its nature is capable of no fear, and in general of no desire or emotion, and is therefore indifferent to being and not being, the mere subject of knowledge, the intellect, whose existence consists in its relation to the world of idea, *i.e.*, the objective world, whose correlative it is, and with whose existence its own is ultimately one. Thus, although the individual consciousness does not survive death, yet that

survives it which alone struggles against it — the will. This also explains the contradiction that from the standpoint of knowledge philosophers have always proved with cogent reasons that death is no evil; yet the fear of death remains inevitable for all, because it is rooted, not in knowledge, but in the will. It is also a result of the fact that only the will, and not the intellect, is indestructible, that all religions and philosophies promise a reward in eternity only to the virtues of the will, or heart, not to those of the intellect, or head.

The following may also serve to illustrate this consideration. The will, which constitutes our true being, is of a simple nature; it merely wills, and does not know. The subject of knowledge, on the other hand, is a secondary phenomenon, arising from the objectification of the will; it is the point of unity of the sensibility of the nervous system, as it were the focus in which the rays of the activity of all the parts of the brain unite. With this, then, it must perish. In self-consciousness, as that which alone knows, it stands over against the will as its spectator, and, although sprung from it, knows it as something different from itself, something foreign to it, and consequently also only empirically, in time, by degrees, in its successive excitements and acts, and also learns its decisions only a posteriori, and often very indirectly. This explains the fact that our own nature is a riddle to us, *i.e.*, to our intellect, and that the individual regards itself as having newly arisen and as perishable; although its true nature is independent of time, thus is eternal. As now the will does not know, so conversely the intellect, or the subject of knowledge, is simply and solely knowing, without ever willing. This can be proved even physically in the fact that, as was already mentioned in the second book, according to Bichat, the various emotions directly affect all parts of the organism and disturb their functions, with the exception of the brain, which can only be affected by them very indirectly, *i.e.*, just in consequence of those disturbances (*De la vie et de la mort*, art. 6, § 2). But from this it follows that the subject of knowledge, for itself and as such, cannot take part or interest in anything, but for it the being or not being of everything, nay, even of its own self, is a matter of indifference. Now why should this purely neutral being be immortal? It ends with the temporal manifestation of the will, *i.e.*, the individual, as it arose with it. It is the lantern which is extinguished when it has served its end. The intellect, like the perceptible world which exists only in it, is a mere phenomenon; but the finiteness of both does not affect that of which they are the phenomenal

appearance. The intellect is the function of the cerebral nervous system; but the latter, like the rest of the body, is the objectivity of the will. Therefore the intellect depends upon the somatic life of the organism; but this itself depends upon the will. The organised body may thus, in a certain sense, be regarded as the link between the will and the intellect; although really it is only the will itself exhibiting itself spatially in the perception of the intellect. Death and birth are the constant renewal of the consciousness of the will, in itself without end and without beginning, which alone is, as it were, the substance of existence (but each such renewal brings a new possibility of the denial of the will to live). Consciousness is the life of the subject of knowledge, or the brain, and death is its end. And therefore, finally, consciousness is always new, in each case beginning at the beginning. The will alone is permanent; and, moreover, it is it alone that permanence concerns; for it is the will to live. The knowing subject for itself is not concerned about anything. In the ego, however, the two are bound up together. In every animal existence the will has achieved an intellect which is the light by which it here pursues its ends. It may be remarked by the way that the fear of death may also partly depend upon the fact that the individual will is so loath to separate from the intellect which has fallen to its lot through the course of nature, its guide and guard, without which it knows that it is helpless and blind.

Finally, this explanation also agrees with the commonplace moral experience which teaches us that the will alone is real, while its objects, on the other hand, as conditioned by knowledge, are only phenomena, are only froth and vapour, like the wine which Mephistopheles provided in Auerbach's cellar: after every sensuous pleasure we also say, "And yet it seemed as I were drinking wine."

The terrors of death depend for the most part upon the false illusion that now the ego vanishes and the world remains. But rather is the opposite the case; the world vanishes, but the inmost kernel of the ego, the supporter and producer of that subject, in whose idea alone the world has its existence, remains. With the brain the intellect perishes, and with the intellect the objective world, its mere idea. That in other brains, afterwards as before, a similar world lives and moves is, with reference to the intellect which perishes, a matter of indifference. If, therefore, reality proper did not lie in the will, and if the moral existence were not that which extends beyond death, then, since the intellect, and with it its world, is extinguished,

the true nature of things in general would be no more than an endless succession of short and troubled dreams, without connection among themselves; for the permanence of unconscious nature consists merely in the idea of time of conscious nature. Thus a world-spirit dreaming without end or aim, dreams which for the most part are very troubled and heavy, would then be all in all.

When, now, an individual experiences the fear of death, we have really before us the extraordinary, nay, absurd, spectacle of the lord of the worlds, who fills all with his being, and through whom alone everything that is has its existence, desponding and afraid of perishing, of sinking into the abyss of eternal nothingness; — while, in truth, all is full of him, and there is no place where he is not, no being in which he does not live; for it is not existence that supports him, but he that supports existence. Yet it is he who desponds in the individual who suffers from the fear of death, for he is exposed to the illusion produced by the principium individuationis that his existence is limited to the nature which is now dying. This illusion belongs to the heavy dream into which, as the will to live, he has fallen. But one might say to the dying individual: "Thou ceasest to be something which thou hadst done better never to become."

So long as no denial of the will takes place, what death leaves untouched is the germ and kernel of quite another existence, in which a new individual finds itself again, so fresh and original that it broods over itself in astonishment. What sleep is for the individual, death is for the will as thing in itself. It would not endure to continue the same actions and sufferings throughout an eternity without true gain, if memory and individuality remained to it. It flings them off, and this is lethe; and through this sleep of death it reappears refreshed and fitted out with another intellect, as a new being— "a new day tempts to new shores."

As the self-asserting will to live man has the root of his existence in the species. Accordingly death is the loss of one individuality and the assumption of another, consequently a change of individuality under the exclusive guidance of one's own will. For in this alone lies the eternal power which could produce its existence with its ego, yet, on account of its nature, was not able to maintain it in existence. For death is the démenti which the essence (essentia) of every one receives in its claim to existence (existentia), the appearance of a contradiction which lies in every individual existence:

“For all that arises
Is worthy of being destroyed.”

But an infinite number of such existences, each with its ego, stands within reach of this power, thus of the will, which, however, will again prove just as transitory and perishable. Since now every ego has its separate consciousness, that infinite number of them is, with reference to such an ego, not different from a single one. From this point of view it appears to me not accidental that ævum, αἰών, signifies both the individual term of life and infinite time. Indeed from this point of view it may be seen, although indistinctly, that ultimately and in themselves both are the same; and according to this there would really be no difference whether I existed only through my term of life or for an infinite time.

Certainly, however, we cannot obtain an idea of all that is said above entirely without time-concepts; yet when we are dealing with the thing in itself these ought to be excluded. But it belongs to the unalterable limitations of our intellect that it can never entirely cast off this first and most immediate form of all its ideas, in order to operate without it. Therefore we certainly come here upon a kind of metempsychosis, although with the important difference that it does not concern the whole ψυχη, not the knowing being, but the will alone; and thus, with the consciousness that the form of time only enters here as an unavoidable concession to the limitation of our intellect, so many absurdities which accompany the doctrine of metempsychosis disappear. If, indeed, we now call in the assistance of the fact, to be explained in chapter 43, that the character, *i.e.*, the will, is inherited from the father, and the intellect, on the other hand, from the mother, it agrees very well with our view that the will of a man, in itself individual, separated itself in death from the intellect received from the mother in generation, and in accordance with its now modified nature, under the guidance of the absolutely necessary course of the world harmonising with this, received through a new generation a new intellect, with which it became a new being, which had no recollection of an earlier existence; for the intellect, which alone has the faculty of memory, is the mortal part or the form, while the will is the eternal part, the substance. In accordance with this, this doctrine is more correctly denoted by the word palingenesis than by metempsychosis. These constant new births, then, constitute the succession of the life-dreams of a will which in itself is indestructible, until, instructed and improved by so much and such various

successive knowledge in a constantly new form, it abolishes or abrogates itself.

The true and, so to speak, esoteric doctrine of Buddhism, as we have come to know it through the latest investigations, also agrees with this view, for it teaches not metempsychosis, but a peculiar palingenesis, resting upon a moral basis which it works out and explains with great profundity. This may be seen from the exposition of the subject, well worth reading and pondering, which is given in Spence Hardy's "Manual of Buddhism," pp. 394-96 (with which compare pp. 429, 440, and 445 of the same book), the confirmation of which is to be found in Taylor's "*Prabodh Chandro Daya*," London, 1812, p. 35; also in Sangermano's "Burmese Empire," p. 6, and in the "Asiatic Researches," vol. vi. p. 179, and vol. ix. p. 256. The very useful German compendium of Buddhism by Köppen is also right upon this point. Yet for the great mass of Buddhists this doctrine is too subtle; therefore to them simple metempsychosis is preached as a comprehensible substitute.

Besides, it must not be neglected that even empirical grounds support a palingenesis of this kind. As a matter of fact there does exist a connection between the birth of the newly appearing beings and the death of those that are worn out. It shows itself in the great fruitfulness of the human race which appears as a consequence of devastating diseases. When in the fourteenth century the black death had for the most part depopulated the old world, a quite abnormal fruitfulness appeared among the human race, and twin-births were very frequent. The circumstance was also very remarkable that none of the children born at this time obtained their full number of teeth; thus nature, exerting itself to the utmost, was niggardly in details. This is related by F. Schnurrer, "*Chronik der Seuchen*," 1825. Casper also, "*Ueber die wahrscheinliche Lebensdauer des Menschen*," 1835, confirms the principle that the number of births in a given population has the most decided influence upon the length of life and mortality in it, as this always keeps pace with the mortality: so that always and everywhere the deaths and the births increase and decrease in like proportion; which he places beyond doubt by an accumulation of evidence collected from many lands and their various provinces. And yet it is impossible that there can be a physical causal connection between my early death and the fruitfulness of a marriage with which I have nothing to do, or conversely. Thus here the metaphysical appears undeniably and in a stupendous manner as the immediate ground of explanation of the physical. Every new-born being indeed comes fresh and

blithe into the new existence, and enjoys it as a free gift: but there is, and can be, nothing freely given. Its fresh existence is paid for by the old age and death of a worn-out existence which has perished, but which contained the indestructible seed out of which this new existence has arisen: they are one being. To show the bridge between the two would certainly be the solution of a great riddle.

The great truth which is expressed here has never been entirely unacknowledged, although it could not be reduced to its exact and correct meaning, which is only possible through the doctrine of the primacy and metaphysical nature of the will and the secondary, merely organic nature of the intellect. We find the doctrine of metempsychosis, springing from the earliest and noblest ages of the human race, always spread abroad in the earth as the belief of the great majority of mankind, nay, really as the teaching of all religions, with the exception of that of the Jews and the two which have proceeded from it: in the most subtle form, however, and coming nearest to the truth, as has already been mentioned, in Buddhism. Accordingly, while Christians console themselves with the thought of meeting again in another world, in which one regains one's complete personality and knows oneself at once, in those other religions the meeting again is already going on now, only incognito. In the succession of births, and by virtue of metempsychosis or palingenesis, the persons who now stand in close connection or contact with us will also be born along with us at the next birth, and will have the same or analogous relations and sentiments towards us as now, whether these are of a friendly or a hostile description. (*Cf.*, for example, Spence Hardy's "Manual of Buddhism," p. 162.) Recognition is certainly here limited to an obscure intimation, a reminiscence which cannot be brought to distinct consciousness, and refers to an infinitely distant time; — with the exception, however, of Buddha himself, who has the prerogative of distinctly knowing his own earlier births and those of others; — as this is described in the "Jâtaka." But, in fact, if at favourable moment one contemplates, in a purely objective manner, the action of men in reality; the intuitive conviction is forced upon one that it not only is and remains constantly the same, according to the (Platonic) Idea, but also that the present generation, in its true inner nature, is precisely and substantially identical with every generation that has been before it. The question simply is in what this true being consists. The answer which my doctrine gives to this question is well known. The

intuitive conviction referred to may be conceived as arising from the fact that the multiplying-glasses, time and space, lose for a moment their effect. With reference to the universality of the belief in metempsychosis, Obry says rightly, in his excellent book, "*Du Nirvana Indien*," p. 13: "Cette vieille croyance a fait le tour du monde, et était tellement répandue dans la haute antiquité, qu'un docte Anglican l'avait jugée sans père, sans mère, et sans généalogie" (*Ths. Burnet, dans Beausobre, Hist. du Manichéisme*, ii. p. 391). Taught already in the "Vedas," as in all the sacred books of India, metempsychosis is well known to be the kernel of Brahmanism and Buddhism. It accordingly prevails at the present day in the whole of non-Mohammedan Asia, thus among more than half of the whole human race, as the firmest conviction, and with an incredibly strong practical influence. It was also the belief of the Egyptians (Herod., ii. 123), from whom it was received with enthusiasm by Orpheus. Pythagoras, and Plato: the Pythagoreans, however, specially retained it. That it was also taught in the mysteries of the Greeks undeniably follows from the ninth book of Plato's "Laws" (pp. 38 and 42, ed. Bip.) Nemesius indeed (*De nat. hom.*, c. 2) says: "Κοινη μεν οὑν παντες Ἑλληνες, οἱ την ψυχην αθανατον αποφηναμενοι, την μετενσωματωσιν δογματιζουσι." (Communiter igitur omnes Græci, qui animam immortalem statuerunt, eam de uno corpore in aliud transferri censuerunt.) The "Edda" also, especially in the "Völuspá," teaches metempsychosis. Not less was it the foundation of the religion of the Druids (*Cæs. de bello Gall.*, vi.; *A. Pictet, Le mystère des Bardes de l'ile de Bretagne*, 1856). Even a Mohammedan sect in Hindostan, the Bohrahs, of which Colebrooke gives a full account in the "Asiatic Researches," vol. vii. p. 336 *sqq.*, believes in metempsychosis, and accordingly refrains from all animal food. Also among American Indians and negro tribes, nay, even among the natives of Australia, traces of this belief are found, as appears from a minute description given in the *Times* of 29th January 1841 of the execution of two Australian savages for arson and murder. It is said there: "The younger of the two prisoners met his end with a dogged and a determined spirit, as it appeared, of revenge; the only intelligible expressions made use of conveyed an impression that he would rise up a 'white fellow,' which it was considered strengthened his resolution." Also in a book by Ungewitter, "*Der Welttheil Australien*," it is related that the Papuas in Australia regarded the whites as their own relations who had returned to the world. According to all this, the belief in metempsychosis

presents itself as the natural conviction of man, whenever he reflects at all in an unprejudiced manner. It would really be that which Kant falsely asserts of his three pretended Ideas of the reason, a philosopheme natural to human reason, which proceeds from its forms; and when it is not found it must have been displaced by positive religious doctrines coming from a different source. I have also remarked that it is at once obvious to every one who hears of it for the first time. Let any one only observe how earnestly Lessing defends it in the last seven paragraphs of his "*Erziehung des Menschengeschlechts*." Lichtenberg also says in his "*Selbstcharacteristik*:" "I cannot get rid of the thought that I died before I was born." Even the excessively empirical Hume says in his sceptical essay on immortality, p. 23: "The metempsychosis is therefore the only system of this kind that philosophy can hearken to."[31] What resists this belief, which is spread over the whole human race and commends itself alike to the wise and to the vulgar, is Judaism, together with the two religions which have sprung from it, because they teach the creation of man out of nothing, and he has then the hard task of linking on to this the belief in an endless existence a parte post. They certainly have succeeded, with fire and sword, in driving out of Europe and part of Asia that consoling primitive belief of mankind; it is still doubtful for how long. Yet how difficult this was is shown by the oldest Church histories. Most of the heretics were attached to this primitive belief; for example, Simonists, Basilidians, Valentinians, Marcionists, Gnostics, and Manichæans. The Jews themselves have in part fallen into it, as Tertullian and Justinus (in his dialogues) inform us. In the Talmud it is related that Abel's soul passed into the body of Seth, and then into that of Moses. Even the passage of the Bible, Matt. xvi. 13-15, only obtains a rational meaning if we understand it as spoken under the assumption of the dogma of metempsychosis. Luke, it is true, who also has the passage (ix. 18-20), adds the words ὁτι προφητης τις των αρχαιων ανεστῃ, and thus attributes to the Jews the assumption that such an ancient prophet can rise again body and all, which, since they know that he has already lain between six and seven hundred years in his grave, and consequently has long since turned to dust, would be a palpable absurdity. In Christianity, however, the doctrine of original sin, *i.e.*, the doctrine of punishment for the sins of another individual, has taken the place of the transmigration of souls and the expiation in this way of all the sins committed in an earlier life. Both identify, and that with a moral tendency, the existing man with one who has

existed before; the transmigration of souls does so directly, original sin indirectly.

Death is the great reprimand which the will to live, or more especially the egoism, which is essential to this, receives through the course of nature; and it may be conceived as a punishment for our existence.[32] It is the painful loosing of the knot which the act of generation had tied with sensual pleasure, the violent destruction coming from without of the fundamental error of our nature: the great disillusion. We are at bottom something that ought not to be: therefore we cease to be. Egoism consists really in the fact that man limits all reality to his own person, in that he imagines that he lives in this alone and not in others. Death teaches him better, for it destroys this person, so that the true nature of man, which is his will, will henceforth live only in other individuals; while his intellect, which itself belonged only to the phenomenon, *i.e.*, to the world as idea, and was merely the form of the external world, also continues to exist in the condition of being idea, *i.e.*, in the objective being of things as such, thus also only in the existence of what was hitherto the external world. His whole ego thus lives from this time forth only in that which he had hitherto regarded as non-ego: for the difference between external and internal ceases. We call to mind here that the better man is he who makes the least difference between himself and others, does not regard them as absolute non-ego, while for the bad man this difference is great, nay, absolute. I have worked this out in my prize essay on the foundation of morals. According to what was said above, the degree in which death can be regarded as the annihilation of the man is in proportion to this difference. But if we start from the fact that the distinction of outside me and in me, as a spatial distinction, is only founded in the phenomenon, not in the thing in itself, thus is no absolutely real distinction, then we shall see in the losing of our own individuality only the loss of a phenomenon, thus only an apparent loss. However much reality that distinction has in the empirical consciousness, yet from the metaphysical standpoint the propositions, "I perish, but the world endures," and "The world perishes but I endure," are at bottom not really different.

But, besides all this, death is the great opportunity no longer to be I; — to him who uses it. During life the will of man is without freedom: his action takes place with necessity upon the basis of his unalterable character in the chain of motives. But every one remembers much that he has done, and on account of which he is by no means satisfied with himself. If now he

were to go on living, he would go on acting in the same way, on account of the unalterable nature of his character. Accordingly he must cease to be what he is in order to be able to arise out of the germ of his nature as a new and different being. Therefore death looses these bonds; the will again becomes free; for freedom lies in the Esse, not in the Operari. "Finditur nodus cordis, dissolvuntur omnes dubitationes, ejusque opera evanescunt," is a very celebrated saying of the Vedas, which all Vedantic writers frequently repeat.[33] Death is the moment of that deliverance from the one-sidedness of an individuality which does not constitute the inmost kernel of our being, but is rather to be thought of as a kind of aberration of it. The true original freedom re-enters at this moment, which, in the sense indicated, may be regarded as a restitutio in integrum. The peace and quietness upon the countenance of most dead persons seems to have its origin in this. Quiet and easy is, as a rule, the death of every good man: but to die willingly, to die gladly, to die joyfully, is the prerogative of the resigned, of him who surrenders and denies the will to live. For only he wills to die really, and not merely apparently, and consequently he needs and desires no continuance of his person. The existence which we know he willingly gives up: what he gets instead of it is in our eyes nothing, because our existence is, with reference to that, nothing. The Buddhist faith calls it Nirvana,[34] *i.e.*, extinction.

Chapter XLII. The Life Of The Species.

In the preceding chapter it was called to mind that the (Platonic) Ideas of the different grades of beings, which are the adequate objectification of the will to live, exhibit themselves in the knowledge of the individual, which is bound to the form of time, as the species, *i.e.*, as the successive individuals of one kind connected by the bond of generation, and that therefore the species is the Idea (εἶδος, species) broken up in time. Accordingly the true nature of every living thing lies primarily in its species: yet the species again has its existence only in the individuals. Now, although the will only attains to self-consciousness in the individual, thus knows itself immediately only as the individual, yet the deep-seated consciousness that it is really the species in which his true nature objectifies itself appears in the fact that for the individual the concerns of the species as such, thus the relations of the sexes, the production and nourishment of the offspring, are of incomparably greater importance and consequence than everything else. Hence, then, arises in the case of the brutes, heat or rut (an excellent description of the vehemence of which will be found in Burdach's "Physiology," vol. i. §§ 247, 257), and, in the case of man, the careful and capricious selection of the other individual for the satisfaction of the sexual impulse, which can rise to the height of passionate love, to the fuller investigation of which I shall devote a special chapter: hence also, finally the excessive love of parents for their offspring.

In the supplements to the second book the will was compared to the root and the intellect to the crown of the tree; and this is the case inwardly or psychologically. But outwardly or physiologically the genitals are the root and the head the crown. The nourishing part is certainly not the genitals, but the villi of the intestines: yet not the latter but the former are the root; because through them the individual is connected with the species in which it is rooted. For physically the individual is a production of the species, metaphysically a more or less perfect picture of the Idea, which, in the form of time, exhibits itself as species. In agreement with the relation expressed here, the greatest vitality, and also the decrepitude of the brain and the genital organs, is simultaneous and stands in connection. The sexual impulse is to be regarded as the inner life of the tree (the species) upon

which the life of the individual grows, like a leaf that is nourished by the tree, and assists in nourishing the tree; this is why that impulse is so strong, and springs from the depths of our nature. To castrate an individual means to cut him off from the tree of the species upon which he grows, and thus severed, leave him to wither: hence the degradation of his mental and physical powers. That the service of the species, *i.e.*, fecundation, is followed in the case of every animal individual by momentary exhaustion and debility of all the powers, and in the case of most insects indeed by speedy death, on account of which Celsus said, "Seminis emissio est partis animæ jactura;" that in the case of man the extinction of the generative power shows that the individual approaches death; that excessive use of this power at every age shortens life, while, on the other hand, temperance in this respect increases all the powers, and especially the muscular powers, on which account it was part of the training of the Greek athletes; that the same restraint lengthens the life of the insect even to the following spring; all this points to the fact that the life of the individual is at bottom only borrowed from the species, and that all vital force is, as it were, force of the species restricted by being dammed up. But this is to be explained from the fact that the metaphysical substratum of life reveals itself directly in the species and only by means of this in the individual. Accordingly the Lingam with the Yoni, as the symbol of the species and its immortality, is worshipped in India, and, as the counterpoise of death, is ascribed as an attribute to the very divinity who presides over death, Siva.

But without myth or symbol, the vehemence of the sexual impulse, the keen intentness and profound seriousness with which every animal, including man, pursues its concerns, shows that it is through the function which serves it that the animal belongs to that in which really and principally its true being lies, the species; while all other functions and organs directly serve only the individual, whose existence is at bottom merely secondary. In the vehemence of that impulse, which is the concentration of the whole animal nature, the consciousness further expresses itself that the individual does not endure, and therefore all must be staked on the maintenance of the species, in which its true existence lies.

To illustrate what has been said, let us now imagine a brute in rut, and in the act of generation. We see a seriousness and intentness never known in it at any other time. Now what goes on in it? Does it know that it must die, and that through its present occupation a new individual, which yet entirely

resembles itself, will arise in order to take its place? Of all this it knows nothing, for it does not think. But it is as intently careful for the continuance of the species in time as if it knew all that. For it is conscious that it desires to live and exist, and it expresses the highest degree of this volition in the act of generation; this is all that then takes place in its consciousness. This is also quite sufficient for the permanence of the kind; just because the will is the radical and knowledge the adventitious. On this account the will does not require to be guided by knowledge throughout; but whenever in its primitive originality it has resolved, this volition will objectify itself of its own accord in the world of the idea. If now in this way it is that definite animal form which we have thought of that wills life and existence, it does not will life and existence in general, but in this particular form. Therefore it is the sight of its form in the female of its species that stimulates the will of the brute to the act of generation. This volition of the brute, when regarded from without and under the form of time, presents itself as such an animal form maintained through an infinite time by the constantly repeated replacement of one individual by another, thus by the alternation of death and reproduction, which so regarded appear only as the pulse-beats of that form (ιδεα, εἱδος, species) which endures through all time. They may be compared to the forces of attraction and repulsion in which matter consists. That which is shown here in the brute holds good also of man; for although in him the act of generation is accompanied by complete knowledge of its final cause, yet it is not guided by this knowledge, but proceeds directly from the will to live as its concentration. It is accordingly to be reckoned among instinctive actions. For in reproduction the brute is just as little guided by knowledge of the end as in mechanical instincts; in these also the will manifests itself, in the main, without the mediation of knowledge, which here, as there, is only concerned with details. Reproduction is, to a certain extent, the most marvellous of all instincts, and its work the most astonishing.

These considerations explain why the sexual desire has a very different character from every other; it is not only the strongest, but even specifically of a more powerful kind than any other. It is everywhere tacitly assumed as necessary and inevitable, and is not, like other desires, a matter of taste and disposition. For it is the desire which even constitutes the nature of man. In conflict with it no motive is so strong that it would be certain of victory. It is so pre-eminently the chief concern that no other pleasures make up for

the deprivation of its satisfaction; and, moreover, for its sake both brute and man undertake every danger and every conflict. A very naïve expression of this disposition is the well-known inscription on the door of the fornix at Pompeii, decorated with the phallus: “Heic habitat felicitas:” this was for those going in naïve, for those coming out ironical, and in itself humorous. On the other hand, the excessive power of the sexual passion is seriously and worthily expressed in the inscription which (according to Theon of Smyrna, *De Musica*, c. 47), Osiris had placed upon the column he erected to the eternal gods: “To Eros, the spirit, the heaven, the sun, the moon, the earth, the night, the day, and the father of all that is and that shall be;” also in the beautiful apostrophe with which Lucretius begins his work:

“Æneadum genetrix, hominum divomque voluptas,
Alma Venus cet.”

To all this corresponds the important rôle which the relation of the sexes plays in the world of men, where it is really the invisible central point of all action and conduct, and peeps out everywhere in spite of all veils thrown over it. It is the cause of war and the end of peace, the basis of what is serious, and the aim of the jest, the inexhaustible source of wit, the key to all allusions, and the meaning of all mysterious hints, of all unspoken offers and all stolen glances, the daily meditation of the young, and often also of the old, the hourly thought of the unchaste, and even against their will the constantly recurring imagination of the chaste, the ever ready material of a joke, just because the profoundest seriousness lies at its foundation. It is, however, the piquant element and the joke of life that the chief concern of all men is secretly pursued and ostensibly ignored as much as possible. But, in fact, we see it every moment seat itself, as the true and hereditary lord of the world, out of the fulness of its own strength, upon the ancestral throne, and looking down from thence with scornful glances, laugh at the preparations which have been made to bind it, imprison it, or at least to limit it and wherever it is possible to keep it concealed, or even so to master it that it shall only appear as a subordinate, secondary concern of life. But all this agrees with the fact that the sexual passion is the kernel of the will to live, and consequently the concentration of all desire; therefore in the text I have called the genital organs the focus of the will. Indeed, one may say man is concrete sexual desire; for his origin is an act of copulation and his wish of wishes is an act of copulation, and this tendency alone perpetuates and holds together his whole phenomenal existence. The will to live

manifests itself indeed primarily as an effort to sustain the individual; yet this is only a step to the effort to sustain the species, and the latter endeavour must be more powerful in proportion as the life of the species surpasses that of the individual in duration, extension, and value. Therefore sexual passion is the most perfect manifestation of the will to live, its most distinctly expressed type; and the origin of the individual in it, and its primacy over all other desires of the natural man, are both in complete agreement with this.

One other remark of a physiological nature is in place here, a remark which throws light upon my fundamental doctrine expounded in the second book. As the sexual impulse is the most vehement of desires, the wish of wishes, the concentration of all our volition, and accordingly the satisfaction of it which exactly corresponds to the individual wish of any one, that is, the desire fixed upon a definite individual, is the summit and crown of his happiness, the ultimate goal of his natural endeavours, with the attainment of which everything seems to him to have been attained, and with the frustrating of which everything seems to him to have been lost: — so we find, as its physiological correlative, in the objectified will, thus in the human organism, the sperm or semen as the secretion of secretions, the quintessence of all animal fluids, the last result of all organic functions, and have in it a new proof of the fact that the body is only the objectivity of the will, *i.e.*, is the will itself under the form of the idea.

With reproduction is connected the maintenance of the offspring, and with the sexual impulse, parental love; and thus through these the life of the species is carried on. Accordingly the love of the brute for its young has, like the sexual impulse, a strength which far surpasses that of the efforts which merely concerns itself as an individual. This shows itself in the fact that even the mildest animals are ready to undertake for the sake of their young even the most unequal battle for life and death, and with almost all species of animals the mother encounters any danger for the protection of her young, nay, in many cases even faces certain death. In the case of man this instinctive parental love is guided and directed by reason, *i.e.*, by reflection. Sometimes, however, it is also in this way restricted, and with bad characters this may extend to the complete repudiation of it. Therefore we can observe its effects most purely in the lower animals. In itself, however, it is not less strong in man; here also, in particular cases, we see it entirely overcome self-love, and even extend to the sacrifice of life. Thus,

for example, the French newspapers have just announced that at Cahors, in the department of Lot, a father has taken his own life in order that his son, who had been drawn for military service, should be the eldest son of a widow, and therefore exempt (*Galignani's Messenger* of 22d June 1843). Yet in the case of the lower animals, since they are capable of no reflection, the instinctive maternal affection (the male is generally ignorant of his paternity) shows itself directly and unsophisticated, and therefore with perfect distinctness and in its whole strength. At bottom it is the expression of the consciousness in the brute that its true being lies more immediately in the species than in the individual, and therefore, when necessary, it sacrifices its life that the species may be maintained in the young. Thus here, as also in the sexual impulse, the will to live becomes to a certain extent transcendent, for its consciousness extends beyond the individual, in which it is inherent, to the species. In order to avoid expressing this second manifestation of the life of the species in a merely abstract manner, and to present it to the reader in its magnitude and reality, I will give a few examples of the extraordinary strength of instinctive maternal affection.

The sea-otter, when pursued, seizes its young one and dives with it; when it comes up again to take breath, it covers the young one with its body, and receives the harpoon of the hunter while the young one is escaping. A young whale is killed merely to attract the mother, who hurries to it and seldom forsakes it so long as it still lives, even although she is struck with several harpoons (Scoresby's "Journal of a Whaling Voyage;" from the English of Kreis, p. 196). At Three Kings Island, near New Zealand, there are colossal seals called sea-elephants (phoca proboscidea). They swim round the island in regular herds and feed upon fishes, but yet have certain terrible enemies below water unknown to us, by whom they are often severely wounded; hence their swimming together requires special tactics. The females bring forth their young upon the shore; while they are suckling them, which lasts from seven to eight weeks, all the males form a circle round them in order to prevent them, driven by hunger, from entering the sea, and if this is attempted they prevent it by biting. Thus they all fast together for between seven and eight weeks, and all become very thin, simply in order that the young may not enter the sea before they are able to swim well and observe the necessary tactics which are then taught them with blows and bites (Freycinet, *Voy. aux terres Australes*, 1826). We also see here how parental affection, like every strong exertion of the will (*cf.*

chap. xix. 6), heightens the intelligence. Wild ducks, white-throats, and many other birds, when the sportsman comes near their nest, fly in front of him with loud cries and flap about as if their wings were injured, in order to attract his attention from their young to themselves. The lark tries to entice the dog away from its nest by exposing itself. In the same way hinds and does induce the hunter to pursue them in order that their young may not be attacked. Swallows have flown into burning houses to rescue their young or perish with them. At Delft, in a great fire, a stork allowed itself to be burnt in its nest rather than forsake its tender young, which could not yet fly (Hadr. Junius, *Descriptio Hollandiæ*). Mountain-cocks and woodcocks allow themselves to be taken upon the nest when brooding. Muscicapa tyrannus protects its nest with remarkable courage, and defends itself against eagles. An ant has been cut in two, and the fore half been seen to bring the pupæ to a place of safety. A bitch whose litter had been cut out of her belly crept up to them dying, caressed them, and began to whine violently only when they were taken from her (Burdach, *Physiologie als Erfahrungswissenschaft*, vol. ii. and iii.).

Chapter XLIII. On Heredity.

The most ordinary experience teaches that in generation the combined seed of the parents not only propagates the peculiarities of the species, but also those of the individual, as far as bodily (objective, external) qualities are concerned, and this has also always been recognised —

"Naturæ sequitur semina quisque suæ."

— Catull.

Now whether this also holds good of mental (subjective, internal) qualities, so that these also are transmitted by the parents to the children, is a question which has already often been raised, and almost always answered in the affirmative. More difficult, however, is the problem whether it is possible to distinguish what belongs to the father and what to the mother, thus what is the mental inheritance which we receive from each of our parents. If now we cast upon this problem the light of our fundamental knowledge that the will is the true being, the kernel, the radical element in man, and the intellect, on the other hand, is what is secondary, adventitious, the accident of that substance; before questioning experience we will assume it as at least probable that the father, as sexus potior and the procreative principle, imparts the basis, the radical element, of the new life, thus the will, and the mother, as sexus sequior and merely conceiving principle, imparts the secondary element, the intellect; that thus the man inherits his moral nature, his character, his inclinations, his heart, from the father, and, on the other hand, the grade, quality, and tendency of his intelligence from the mother. Now this assumption actually finds its confirmation in experience; only this cannot be decided by a physical experiment upon the table, but results partly from the careful and acute observation of many years, and partly from history.

One's own experience has the advantage of complete certainty and the greatest speciality, and this outweighs the disadvantage that arises from it, that its sphere is limited and its examples not generally known. Therefore, primarily, I refer every one to his own experience. First of all let him consider himself, confess to himself his inclinations and passions, his characteristic errors and weaknesses, his vices, and also his excellences and virtues, if he has any. Then let him think of his father, and he cannot fail to recognise all these characteristic traits in him also. On the other hand, he

will often find his mother of an entirely different character, and a moral agreement with her will very seldom occur, indeed only through the exceptional accident of a similarity of the character of the two parents. Let him make this examination, for example, with reference to quick temper or patience, avarice or prodigality, inclination to sensuality, or to intemperance, or to gambling, hard-heartedness or kindliness, honesty or hypocrisy, pride or condescension, courage or cowardice, peaceableness or quarrelsomeness, placability or resentfulness, &c. Then let him make the same investigation with regard to all those whose characters and whose parents he has accurately known. If he proceeds attentively, with correct judgment, and candidly, the confirmation of our principle will not be lacking. Thus, for example, he will find the special tendency to lie, which belongs to many men, equally present in two brothers, because they have inherited it from the father; on this account also the comedy, "The Liar and his Son," is psychologically correct. However, two inevitable limitations must here be borne in mind, which only open injustice could interpret as evasions. First, pater semper incertus. Only a decided physical resemblance to the father removes this limitation; a superficial resemblance, on the other hand, is not sufficient to do so; for there is an after-effect of earlier impregnation by virtue of which the children of the second marriage have sometimes still a slight resemblance to the first husband, and children begotten in adultery to the legitimate father. Such an after-effect has been still more distinctly observed in the case of brutes. The second limitation is, that in the son the moral character of the father certainly appears, yet under the modification which it has received through another and often very different intellect (the inheritance from the mother), and thus a correction of the observation becomes necessary. This modification may be important or trifling in proportion to that difference, but it can never be so great that the fundamental traits of the paternal character do not always appear under it recognisably enough, like a man who has disguised himself by an entirely different kind of dress, wig, and beard. For example, if by inheritance from the mother a man is pre-eminently endowed with reason, thus with the power of reflection and deliberation, the passions inherited from his father are partly bridled by this, partly concealed, and accordingly only attain to a methodical, systematic, or secret manifestation, and thus a very different phenomenon from that of the father, who perhaps had only a very limited mind, will then result; and in the same way the converse case may occur.

The inclinations and passions of the mother, on the other hand, do not reappear at all in the children, often indeed their opposite.

Historical examples have the advantage over those of private life of being universally known; but, on the other hand, they are of course impaired by the uncertainty and frequent falsification of all tradition, and especially also by the fact that as a rule they only contain the public, not the private life, and consequently only the political actions, not the finer manifestations of character. However, I wish to support the truth we are speaking of by a few historical examples, to which those who have made a special study of history can no doubt add a far larger number of equally pertinent cases.

It is well known that P. Decius Mus sacrificed his life for his country with heroic nobleness; for, solemnly committing himself and the enemy to the infernal deities, with covered face he plunged into the army of the Latins. About forty years later his son, of the same name, did exactly the same thing in the war against the Gauls (Liv. viii. 6; x. 28). Thus a thorough proof of the Horatian fortes creantur fortibus et bonis: the converse of which is thus given by Shakspeare —

"Cowards father cowards, and base things sire base."

— Cymbeline, iv. 2.

Early Roman history presents to us whole families whose members in long succession distinguished themselves by devoted patriotism and courage; such were the *gens Fabia* and the *gens Fabricia*. Again, Alexander the Great was fond of power and conquest, like his father Philip. The pedigree of Nero which, with a moral intention, Suetonius (c. 4 *et* 5) gives at the beginning of his sketch of this monster is very well worth considering. It is the *gens Claudia* he describes, which flourished in Rome through six centuries, and produced not only capable, but arrogant and cruel men. From it sprang Tiberius, Caligula, and finally Nero. In his grandfather, and still more strongly in his father, all those atrocious qualities show themselves, which could only attain their perfect development in Nero, partly because his higher position afforded them freer scope, partly because he had for his mother the irrational Bacchante, Agrippina, who could impart to him no intellect to bridle his passions. Quite in our sense, therefore, Suetonius relates that at his birth præsagio fuit etiam Domitii, patris, vox, inter gratulationes amicorum, negantis, quidquam ex se et Agrippina, nisi detestabile et malo publico nasci potuisse. On the other hand, Cimon was

the son of Miltiades, and Hannibal of Hamilcar, and the Scipios make up a whole family of heroes and noble defenders of their country. But the son of Pope Alexander VI. was his hideous image, Cæsar Borgia. The son of the notorious Duke of Alba was just as cruel and wicked a man as his father. The malicious and unjust Philip IV. of France, who is specially known by his cruel torture and execution of the knights templars, had for his daughter Isabella, wife of Edward II. of England, who rebelled against her husband, took him prisoner, and after he had signed his abdication, since the attempt to kill him by ill-usage was unsuccessful, caused him to be put to death in prison in a manner which is too horrible for me to care to relate. The blood-thirsty tyrant and defensor fidei, Henry VIII. of England had a daughter by his first marriage, Queen Mary, equally distinguished for bigotry and cruelty, who from her numerous burnings of heretics has won the name of Bloody Mary. His daughter by his second marriage, Elizabeth, received an excellent understanding from her mother, Anne Boleyn, which prevented bigotry and curbed the parental character in her, yet did not do away with it; so that it still always shone through on occasions, and distinctly appeared in her cruel treatment of Mary of Scotland. Van Geuns[35] tells a story, after Marcus Donatus, of a Scotch girl whose father had been burnt as a highway robber and a cannibal when she was only one year old. Although she was brought up among quite different people, there developed in her the same craving for human flesh, and being caught in the act of satisfying it, she was buried alive. In the *Freimüthigen* of the 13th July 1821 we read that in the department of Aube the police pursued a girl because she had murdered two children, whom she ought to have taken to the foundling hospital, in order to keep the little money given to the children. At last the police found the girl on the road to Paris, near Romilly, drowned, and her own father gave himself up as her murderer. Finally, let me mention a couple of cases which have occurred recently, and have therefore only the newspapers as their vouchers. In October 1836 a Count Belecznai was condemned to death in Hungary because he had murdered an official and severely wounded his own relations. His elder brother was executed earlier as a patricide, and his father also had been a murderer (*Frankfurter Postzeitung* of the 26th October 1836). A year later the youngest brother of this Count, in the same street where the latter had murdered the official, fired a pistol at the steward of his estates, but missed him (*Frankfurter Journal*, 16th September 1837). In the *Frankfurter Postzeitung* of the 19th November 1857 a correspondent

in Paris announces the condemnation to death of a very dangerous highway robber, Lemaire, and his companions, and adds: “The criminal tendency seems hereditary in his family and in those of his confederates, as several of their race have died on the scaffold.” It follows from a passage in the Laws of Plato that similar cases were already known in Greece (*Stob. Flor.*, vol. ii. p. 213). The annals of crime will certainly have many similar pedigrees to show. The tendency to suicide is specially hereditary.

On the other hand, when we see the excellent Marcus Aurelius have the wicked Commodus for a son, this does not not lead us astray; for we know that the *Diva Faustina* was a uxor infamis. On the contrary, we mark this case in order in analogous cases to presume an analogous reason; for example, that Domitian was the full brother of Titus I can never believe, but that Vespasian also was a deceived husband.

Now, as regards the second part of the principle set up thus the inheritance of the intellect from the mother, this enjoys a far more general acceptance than the first part, which in itself appeals to the liberum arbitrium indifferentiæ, while its separate apprehension is opposed by the doctrine of the simplicity and indivisibility of the soul. Even the old and popular expression “mother-wit” shows the early recognition of this second truth, which depends upon the experience both with regard to small and great intellectual endowments, that they are the possession of those whose mothers proportionately distinguished themselves by their intelligence. That, on the other hand, the intellectual qualities of the father are not transmitted to the son is proved both by the fathers and the sons of men distinguished by the most eminent faculties, for, as a rule, they are quite ordinary men, without a trace of the paternal mental gifts. But if now an isolated exception to this experience, so often confirmed, should appear; such, for example, as is presented by Pitt and his father, Lord Chatham, we are warranted in ascribing it to accident, nay, obliged to do so, although, on account of the exceptional rarity of great talents, it is certainly an accident of a most extraordinary kind. Here, however, the rule holds good: it is improbable that the improbable never happens. Besides, great statesmen (as was already mentioned in chapter 22) are so just as much through the qualities of their character, thus through what is inherited from the father, as through the superiority of their mind. On the other hand, among artists, poets, and philosophers, to whose works alone genius is properly ascribed, I know of no case analogous to that. Raphael’s father was certainly a painter,

but not a great one; Mozart's father, and also his son, were musicians, but not great ones. However, it is indeed wonderful that the fate which had destined a very short life to both of these men, each the greatest in his own sphere, as it were by way of compensation, took care, by letting them be born already in their workshop, that, without suffering the loss of time in youth which for the most part occurs in the case of other men of genius, they received even from childhood, through paternal example and instruction, the necessary introduction into the art to which they were exclusively destined. This secret and mysterious power which seems to guide the individual life I have made the subject of special investigations, which I have communicated in the essay, "*Ueber die scheinbare Absichtlichkeit im Schicksale des Einzelnen*" (*Parerga*, vol. i.). It is further to be observed here that there are certain scientific occupations which certainly presuppose good native faculties, yet not those which are really rare and extraordinary; while the principal requirements are zealous efforts, diligence, patience, early instruction, sustained study, and much practice. From this, and not from the inheritance of the intellect of the father, the fact is to be explained that, since the son always willingly follows the path that has been opened up by the father, and almost all businesses are hereditary in certain families, in some sciences also, which before everything demand diligence and persistence, individual families can show a succession of men of merit; such are the Scaligers, the Bernouillis, the Cassinis, the Herschels.

The number of proofs of the actual inheritance of the intellect of the mother would be much greater than it appears if it were not that the character and disposition of the female sex is such that women rarely give public proof of their mental faculties; and therefore these do not become historical, and thus known to posterity. Besides, on account of the weaker nature in general of the female sex, these faculties themselves can never reach the grade in them to which they may afterwards rise in the son; thus, with reference to themselves, we have to estimate their achievements higher in this proportion. Accordingly, in the first instance, only the following examples present themselves as proofs of our truth. Joseph II. was the son of Maria Theresia. Cardanus says in the third chapter, "*De vita propria*:" "Mater mea fuit memoria et ingenio pollens." J. J. Rousseau says in the first book of the "Confessions:" "La beauté de ma mère, son esprit, ses talents, — elle en avait de trop brillans pour son état," &c., and then quotes some delightful lines of hers. D'Alembert was the illegitimate son of Claudine de

Tencin, a woman of superior mind, and the author of several romances and similar works, which met with great approbation in her day, and should even still be enjoyable (see her biography in the "*Blätter für litterarische Unterhaltung*," March 1845, Nos. 71-73). That Buffon's mother was a remarkable woman is shown by the following passage from the "*Voyage à Montbar, par Hérault de Sechelles*," which Flourens quotes in his "*Histoire des travaux de Buffon*," p. 288: "Buffon avait ce principe qu'en général les enfants tenaient de leur mère leurs qualités intellectuelles et morales: et lorsqu'il l'avait développé dans la conversation, il en faisait sur-le-champ l'application à lui-même, en faisant un éloge pompeux de sa mère, qui avait en effet, beaucoup d'esprit, des connaissances étandues, et une tête très bien organisée." That he includes the moral qualities is an error which is either committed by the reporter, or depends upon the fact that his mother had accidentally the same character as himself and his father. The contrary of this is shown in innumerable cases in which the mother and the son have opposite characters. Hence the greatest dramatists could present, in Orestes and Hamlet, mother and son in hostile conflict, in which the son appears as the moral representative and avenger of his father. On the other hand, the converse case, that the son should appear as the moral representative and avenger of the mother against the father, would be revolting and, at the same time, almost absurd. This depends upon the fact that between father and son there is actual identity of nature, which is the will, but between mother and son there is merely identity of intellect, and even this only in a conditioned manner. Between mother and son the greatest moral opposition can exist, between father and son only an intellectual opposition. From this point of view, also, one should recognise the necessity of the Salic law: the woman cannot carry on the race. Hume says in his short autobiography: "Our mother was a woman of singular merit." It is said of Kant's mother in the most recent biography by F. W. Schubert: "According to the judgment of her son himself, she was a woman of great natural understanding. For that time, when there was so little opportunity for the education of girls, she was exceptionally well instructed, and she also continued later to care for her further education by herself. In the course of walks she drew the attention of her son to all kinds of natural phenomena, and tried to explain to him through them the power of God." What a remarkably able, clever, and superior woman Goethe's mother was is now universally known. How much she has been spoken of in literature! while his father has not been

spoken of at all; Goethe himself describes him as a man of subordinate faculties. Schiller's mother was susceptible to poetry, and made verses herself, a fragment of which will be found in his biography by Schwab. Bürger, that genuine poetic genius, to whom perhaps the first place after Goethe among German poets belongs — for compared with his ballads those of Schiller seem cold and laboured — has given an account of his parents which for us is significant, and which his friend and physician, Althof repeats in his biography which appeared in 1798, in these words: "Bürger's father was certainly provided with a variety of knowledge after the manner of study prevalent at the time, and was also a good, honourable man; but he loved his quiet comfort and his pipe of tobacco so much, that, as my friend used to say, he had always first to pull himself together if he was going to apply himself for a quarter of an hour or so to the instruction of his son. His wife was a woman of extraordinary mental endowments, which, however, were so little cultivated that she had scarcely learnt to write legibly. Bürger thought that with proper culture his mother would have been the most famous of her sex, although he several times expressed a strong disapproval of different traits of her moral character. However, he believed that he inherited from his mother some mental gifts, and from his father an agreement with his moral character." Walter Scott's mother was a poetess, and was in communication with the wits of her time, as we learn from the obituary notice of Walter Scott in the *Globe* of 24th September 1832. That poems of hers appeared in print in 1789 I find from an article entitled "Mother-wit," in the *Blätter für litterarische Unterhaltung* of 4th October 1841, published by Brockhaus, which gives a long list of clever mothers of distinguished men, from which I shall only take two: "Bacon's mother was a distinguished linguist, wrote and translated several works, and in all of them showed learning, acuteness, and taste. Boerhave's mother distinguished herself through medical knowledge." On the other hand, Haller has preserved for us a strong proof of the inheritance of the mental weakness of the mother, for he says: "E duabus patriciis sororibus, ob divitias maritos nactis, quum tamen fatuis essent proximæ, novimus in nobilissimas gentes nunc a seculo retro ejus morbi manasse semina, ut etiam in quarta generatione, quintave, omnium posterorum aliqui fatui supersint" (*Elementa physiol.*, Lib. xxix. § 8). Also, according to Esquirol, madness is more frequently inherited from the mother than the father. If,

however, it is inherited from the father, I attribute this to the disposition of the character whose influence occasions it.

It seems to follow from our principle that sons of the same mother have equal mental capacity, and if one should be highly gifted the other must be so also. Sometimes it is so. Examples of this are the Carracci, Joseph and Michael Haydn, Bernard and Andreas Romberg, George and Frederic Cuvier. I would also add the brothers Schlegel, if it were not that the younger, Friedrich, made himself unworthy of the honour of being named along with his excellent, blameless, and highly distinguished brother, August Wilhelm, by the disgraceful obscurantism which in the last quarter of his life he pursued along with Adam Müller. For obscurantism is a sin, possibly not against the Holy Spirit, but yet against the human spirit, which one ought therefore never to forgive, but always and everywhere implacably to remember against whoever has been guilty of it, and take every opportunity of showing contempt for him so long as he lives, nay, after he is dead. But just as often the above result does not take place; for example, Kant's brother was quite an ordinary man. To explain this I must remind the reader of what is said in the thirty-first chapter on the physiological conditions of genius. Not only an extraordinarily developed and absolutely correctly formed brain (the share of the mother) is required, but also a very energetic action of the heart to animate it, *i.e.*, subjectively a passionate will, a lively temperament: this is the inheritance from the father. But this quality is at its height only during the father's strongest years; and the mother ages still more quickly. Accordingly the highly gifted sons will, as a rule, be the eldest, begotten in the full strength of both parents; thus Kant's brother was eleven years younger than him. Even in the case of two distinguished brothers, as a rule, the elder will be the superior. But not only the age, but every temporary ebb of the vital force or other disturbance of health in the parents at the time when the child is begotten may interfere with the part of one or other, and prevent the appearance of a man of eminent talent, which is therefore so exceedingly rare a phenomenon. It may be said, in passing, that in the case of twins the absence of all the differences just mentioned is the cause of the quasi-identity of their nature.

If single cases should be found in which a highly gifted son had a mother who was not mentally distinguished at all, this may be explained from the fact that this mother herself had a phlegmatic father, and on this account her more than ordinarily developed brain was not adequately excited by a

corresponding energy of the circulation — a necessary condition, as I have explained above in chapter 31. Nevertheless, her highly perfected nervous and cerebral system was transmitted to the son, in whose case a father with a lively and passionate disposition and an energetic action of the heart was added, and thus the other physical condition of great mental power first appeared here. Perhaps this was Byron's case, since we nowhere find the mental advantages of his mother mentioned. The same explanation is also to be applied to the case in which the mother of a son of genius who was herself distinguished for mental gifts had a mother who was by no means clever, for the father of the latter has been a man of a phlegmatic disposition.

The inharmonious, disproportionate, ambiguous element in the character of most men might perhaps be referred to the fact that the individual has not a simple origin, but derives the will from the father and the intellect from the mother. The more heterogeneous and ill-adapted to each other the two parents were, the greater will that want of harmony, that inner variance, be. While some excel through their heart and others through their head, there are still others whose excellence lies in a certain harmony and unity of the whole nature, which arises from the fact that in them heart and head are so thoroughly adapted that they mutually support and advance each other; which leads us to assume that the parents were peculiarly suited to each other, and agreed in an exceptional measure.

With reference to the physiological side of the theory set forth, I wish now to mention that Burdach, who erroneously assumes that the same psychical qualities may be inherited now from the father, now from the mother, yet adds (*Physiologie als Erfahrungswissenschaft*, vol. i. § 306): "As a whole, the male element has more influence in determining the irritable life, and the female element, on the other hand, has more influence on the sensibility." What Linné says in the "*Systema naturæ*," Tom. i. p. 8, is also in point here: "Mater prolifera promit, ante generationem, vivum compendium medullare novi animalis suique simillimi, carinam Malpighianam dictum, tanquam plumulam vegetabilium: hoc ex genitura Cor adsociat ramificandum in corpus. Punctum emin saliens ovi incubantis avis ostendit primum cor micans, cerebrumque cum medulla: corculum hoc, cessans a frigore, excitatur calido halitu, premitque bulla aërea, sensim dilatata, liquores, secundum canales fluxiles. Punctum vitalitatis itaque in viventibus est tanquam a prima creatione continuata medullaris vitæ

ramificatio, cum ovum sit gemma medullaris matris a primordio viva, licet non sua ante proprium cor paternum."

If we now connect the conviction we have gained here of the inheritance of the character from the father and the intellect from the mother with our earlier investigation of the wide gulf which nature has placed between man and man in a moral as in an intellectual regard, and also with our knowledge of the absolute unalterableness both of the character and of the mental faculties, we shall be led to the view that a real and thorough improvement of the human race might be attained to not so much from without as from within, thus not so much by instruction and culture as rather upon the path of generation. Plato had already something of the kind in his mind when in the fifth book of his Republic he set forth his wonderful plan for increasing and improving his class of warriors. If we could castrate all scoundrels, and shut up all stupid geese in monasteries, and give persons of noble character a whole harem, and provide men, and indeed complete men, for all maidens of mind and understanding, a generation would soon arise which would produce a better age than that of Pericles. But, without entering into such utopian plans, it might be taken into consideration that if, as, if I am not mistaken, was actually the case among certain ancient nations, castration was the severest punishment after death, the world would be delivered from whole races of scoundrels, all the more certainly as it is well known that most crimes are committed between the age of twenty and thirty.[36] In the same way, it might be considered whether, as regards results, it would not be more advantageous to give the public dowries which upon certain occasions have to be distributed, not, as is now customary, to the girls who are supposed to be the most virtuous, but to those who have most understanding and are the cleverest; especially as it is very difficult to judge as to virtue, for, as it is said, only God sees the heart. The opportunities for displaying a noble character are rare, and a matter of chance; besides, many a girl has a powerful support to her virtue in her plainness; on the other hand, as regards understanding, those who themselves are gifted with it can judge with great certainty after some examination. The following is another practical application. In many countries, among others in South Germany, the bad custom prevails of women carrying burdens, often very considerable, upon the head. This must act disadvantageously upon the brain, which must thereby gradually deteriorate in the female sex of the nation; and since from that sex the male sex receives its brain, the whole

nation becomes ever more stupid; which in many cases is by no means necessary. Accordingly by the abolition of this custom the quantum of intelligence in the whole nation would be increased, which would positively be the greatest increase of the national wealth.

But if now, leaving such practical applications to others, we return to our special point of view, the ethico-metaphysical standpoint — since we connect the content of chapter 41 with that of the present chapter — the following result will present itself to us, which, with all its transcendence, has yet a direct empirical support. It is the same character, thus the same individually determined will, that lives in all the descendants of one stock, from the remote ancestor to the present representative of the family. But in each of these a different intellect is given with it, thus a different degree and a different kind of knowledge. Thus in each of these life presents itself to it from another side and in a different light: it receives a new fundamental view of it, a new instruction. It is true that, since the intellect is extinguished with the individual, that will cannot supplement the insight of one course of life with that of another. But in consequence of each fundamentally new view of life, such as only a renewed personality can impart to it, its willing itself receives a different tendency, thus experiences a modification from it, and what is the chief concern, the will, has, in this new direction, either to assert life anew or deny it. In this way does the arrangement of nature of an ever-changing connection of a will with an intellect, which arises from the necessity of two sexes for reproduction, become the basis of a method of salvation. For by virtue of this arrangement life unceasingly presents new sides to the will (whose image and mirror it is), turns itself about, as it were, without intermission before its sight, allows different and ever different modes of perception to try their effect upon it, so that upon each of these it must decide for assertion or denial, both of which constantly stand open to it, only that, if once denial is chosen, the whole phenomenon ceases for it with death. Now because, according to this, it is just the constant renewal and complete alteration of the intellect for the same will which, as imparting a new view of the world, holds open the path of salvation, and because the intellect comes from the mother, the profound reason may lie here on account of which all nations (with very few and doubtful exceptions) abominate and forbid the marriage of brothers and sisters, nay, even on account of which sexual love does not arise at all between brothers and sisters, unless in very rare exceptions, which depend

upon an unnatural perversity of the instinct, if not upon the fact that one of the two is illegitimate. For from a marriage of brothers and sisters nothing could proceed but constantly ever the same will with the same intellect, as both already exist united in both the parents, thus the hopeless repetition of the phenomenon which has already been.

But if now, in the particular case and close at hand, we contemplate the incredibly great and yet manifest difference of characters — find one so good and philanthropic, another so wicked, nay, ferocious; again, behold one just, honest, and upright, and another completely false, as a sneak, a swindler, a traitor, an incorrigible scoundrel — there discloses itself to us a chasm in our investigation, for in vain we ponder, reflecting on the origin of such a difference. Hindus and Buddhists solve the problem by saying, "It is the consequence of the deeds of the preceding courses of life." This solution is certainly the oldest, also the most comprehensible, and has come from the wisest of mankind; but it only pushes the question further back. Yet a more satisfactory answer will hardly be found. From the point of view of my whole teaching, it remains for me to say that here, where we are speaking of the will as thing in itself, the principle of sufficient reason, as merely the form of the phenomenon, is no longer applicable; with it, however, all why and whence disappear. Absolute freedom just consists in this, that something is not subject at all to the principle of sufficient reason, as the principle of all necessity. Such freedom, therefore, only belongs to the thing in itself. And this is just the will. Accordingly, in its phenomenal manifestation, consequently in the Operari, it is subject to necessity; but in the Esse, where it has determined itself as thing in itself, it is free. Whenever, therefore, we come to this, as happens here, all explanation by means of reasons and consequents ceases, and nothing remains for us but to say that here manifests itself the true freedom of the will, which belongs to it because it is the thing in itself, which, however, just as such, is groundless, *i.e.*, knows no why. But on this account all understanding ceases for us here, because all our understanding depends upon the principle of sufficient reason, for it consists in the mere application of that principle.

Chapter XLIV. The Metaphysics Of The Love Of The Sexes.

"Ye wise men, highly, deeply learned,
Who think it out and know,
How, when, and where do all things pair?
Why do they kiss and love?
Ye men of lofty wisdom, say
What happened to me then;
Search out and tell me where, how, when,
And why it happened thus."
— Bürger.

This chapter is the last of four whose various reciprocal relations, by virtue of which, to a certain extent, they constitute a subordinate whole, the attentive reader will recognise without it being needful for me to interrupt my exposition by recalling them or referring to them.

We are accustomed to see poets principally occupied with describing the love of the sexes. This is as a rule the chief theme of all dramatic works, tragical as well as comical, romantic as well as classical, Indian as well as European. Not less is it the material of by far the largest part of lyrical and also of epic poetry, especially if we class with the latter the enormous piles of romances which for centuries every year has produced in all the civilised countries of Europe as regularly as the fruits of the earth. As regards their main contents, all these works are nothing else than many-sided brief or lengthy descriptions of the passion we are speaking of. Moreover, the most successful pictures of it — such, for example, as Romeo and Juliet, *La Nouvelle Hélöise*, and *Werther* — have gained immortal fame. Yet, when Rochefoucauld imagines that it is the same with passionate love as with ghosts, of which every one speaks, but which no one has seen; and Lichtenberg also in his essay, "*Ueber die Macht der Liebe*," disputes and denies the reality and naturalness of that passion, they are greatly in error. For it is impossible that something which is foreign and contrary to human nature, thus a mere imaginary caricature, could be unweariedly represented by poetic genius in all ages, and received by mankind with unaltered interest; for nothing that is artistically beautiful can be without truth: —

"Rien n'est beau que le vrai; le vrai seul est aimable."

— Boil.

Certainly, however, it is also confirmed by experience, although not by the experience of every day, that that which as a rule only appears as a strong yet still controllable inclination may rise under certain circumstances to a passion which exceeds all others in vehemence, and which then sets aside all considerations, overcomes all obstacles with incredible strength and perseverance, so that for its satisfaction life is risked without hesitation, nay, if that satisfaction is still withheld, is given as the price of it. Werthers and Jacopo Ortis exist not only in romance, but every year can show at least half a dozen of them in Europe: Sed ignotis perierunt mortibus illi; for their sorrows find no other chroniclers than the writers of official registers or the reporters of the newspapers. Yet the readers of the police news in English and French journals will attest the correctness of my assertion. Still greater, however, is the number of those whom the same passion brings to the madhouse. Finally, every year can show cases of the double suicide of a pair of lovers who are opposed by outward circumstances. In such cases, however, it is inexplicable to me how those who, certain of mutual love, expect to find the supremest bliss in the enjoyment of this, do not withdraw themselves from all connections by taking the extremest steps, and endure all hardships, rather than give up with life a pleasure which is greater than any other they can conceive. As regards the lower grades of that passion, and the mere approaches to it, every one has them daily before his eyes, and, as long as he is not old, for the most part also in his heart.

So then, after what has here been called to mind, no one can doubt either the reality or the importance of the matter; and therefore, instead of wondering that a philosophy should also for once make its own this constant theme of all poets, one ought rather to be surprised that a thing which plays throughout so important a part in human life has hitherto practically been disregarded by philosophers altogether, and lies before us as raw material. The one who has most concerned himself with it is Plato, especially in the "Symposium" and the "Phædrus." Yet what he says on the subject is confined to the sphere of myths, fables, and jokes, and also for the most part concerns only the Greek love of youths. The little that Rousseau says upon our theme in the "*Discours sur l'inégalité*" (p. 96, ed. Bip.) is false and insufficient. Kant's explanation of the subject in the third part of the essay, "*Ueber das Gefühl des Schönen und Erhabenen*" (p. 435 *seq.* of Rosenkranz's edition), is very superficial and without practical knowledge,

therefore it is also partly incorrect. Lastly, Platner's treatment of the matter in his "Anthropology" (§ 1347 *seq.*) every one will find dull and shallow. On the other hand, Spinoza's definition, on account of its excessive naïveté, deserves to be quoted for the sake of amusement: "Amor est titillatio, concomitante idea causæ externæ" (*Eth.* iv., prop. 44, *dem.*) Accordingly I have no predecessors either to make use of or to refute. The subject has pressed itself upon me objectively, and has entered of its own accord into the connection of my consideration of the world. Moreover, least of all can I hope for approbation from those who are themselves under the power of this passion, and who accordingly seek to express the excess of their feelings in the sublimest and most ethereal images. To them my view will appear too physical, too material, however metaphysical and even transcendent it may be at bottom. Meanwhile let them reflect that if the object which to-day inspires them to write madrigals and sonnets had been born eighteen years earlier it would scarcely have won a glance from them.

For all love, however ethereally it may bear itself, is rooted in the sexual impulse alone, nay, it absolutely is only a more definitely determined, specialised, and indeed in the strictest sense individualised sexual impulse. If now, keeping this in view, one considers the important part which the sexual impulse in all its degrees and nuances plays not only on the stage and in novels, but also in the real world, where, next to the love of life, it shows itself the strongest and most powerful of motives, constantly lays claim to half the powers and thoughts of the younger portion of mankind, is the ultimate goal of almost all human effort, exerts an adverse influence on the most important events, interrupts the most serious occupations every hour, sometimes embarrasses for a while even the greatest minds, does not hesitate to intrude with its trash interfering with the negotiations of statesmen and the investigations of men of learning, knows how to slip its love letters and locks of hair even into ministerial portfolios and philosophical manuscripts, and no less devises daily the most entangled and the worst actions, destroys the most valuable relationships, breaks the firmest bonds, demands the sacrifice sometimes of life or health, sometimes of wealth, rank, and happiness, nay, robs those who are otherwise honest of all conscience, makes those who have hitherto been faithful, traitors; accordingly, on the whole, appears as a malevolent demon that strives to pervert, confuse, and overthrow everything; — then one will be forced to cry, Wherefore all this noise? Wherefore the straining and storming, the

anxiety and want? It is merely a question of every Hans finding his Grethe.[37] Why should such a trifle play so important a part, and constantly introduce disturbance and confusion into the well-regulated life of man? But to the earnest investigator the spirit of truth gradually reveals the answer. It is no trifle that is in question here; on the contrary, the importance of the matter is quite proportionate to the seriousness and ardour of the effort. The ultimate end of all love affairs, whether they are played in sock or cothurnus, is really more important than all other ends of human life, and is therefore quite worthy of the profound seriousness with which every one pursues it. That which is decided by it is nothing less than the composition of the next generation. The dramatis personæ who shall appear when we are withdrawn are here determined, both as regards their existence and their nature, by these frivolous love affairs. As the being, the existentia, of these future persons is absolutely conditioned by our sexual impulse generally, so their nature, essentia, is determined by the individual selection in its satisfaction, *i.e.*, by sexual love, and is in every respect irrevocably fixed by this. This is the key of the problem: we shall arrive at a more accurate knowledge of it in its application if we go through the degrees of love, from the passing inclination to the vehement passion, when we shall also recognise that the difference of these grades arises from the degree of the individualisation of the choice.

The collective love affairs of the present generation taken together are accordingly, of the whole human race, the serious meditatio compositionis generationis futuræ, e qua iterum pendent innumeræ generationes. This high importance of the matter, in which it is not a question of individual weal or woe, as in all other matters, but of the existence and special nature of the human race in future times, and therefore the will of the individual appears at a higher power as the will of the species; — this it is on which the pathetic and sublime elements in affairs of love depend, which for thousands of years poets have never wearied of representing in innumerable examples; because no theme can equal in interest this one, which stands to all others which only concern the welfare of individuals as the solid body to the surface, because it concerns the weal and woe of the species. Just on this account, then, is it so difficult to impart interest to a drama without the element of love, and, on the other hand, this theme is never worn out even by daily use.

That which presents itself in the individual consciousness as sexual impulse in general, without being directed towards a definite individual of the other sex, is in itself, and apart from the phenomenon, simply the will to live. But what appears in consciousness as a sexual impulse directed to a definite individual is in itself the will to live as a definitely determined individual. Now in this case the sexual impulse, although in itself a subjective need, knows how to assume very skilfully the mask of an objective admiration, and thus to deceive our consciousness; for nature requires this stratagem to attain its ends. But yet that in every case of falling in love, however objective and sublime this admiration may appear, what alone is looked to is the production of an individual of a definite nature is primarily confirmed by the fact that the essential matter is not the reciprocation of love, but possession, *i.e.*, the physical enjoyment. The certainty of the former can therefore by no means console us for the want of the latter; on the contrary, in such a situation many a man has shot himself. On the other hand, persons who are deeply in love, and can obtain no return of it, are contented with possession, *i.e.*, with the physical enjoyment. This is proved by all forced marriages, and also by the frequent purchase of the favour of a woman, in spite of her dislike, by large presents or other sacrifices, nay, even by cases of rape. That this particular child shall be begotten is, although unknown to the parties concerned, the true end of the whole love story; the manner in which it is attained is a secondary consideration. Now, however loudly persons of lofty and sentimental soul, and especially those who are in love, may cry out here about the gross realism of my view, they are yet in error. For is not the definite determination of the individualities of the next generation a much higher and more worthy end than those exuberant feelings and super-sensible soap bubbles of theirs? Nay, among earthly aims, can there be one which is greater or more important? It alone corresponds to the profoundness with which passionate love is felt, to the seriousness with which it appears, and the importance which it attributes even to the trifling details of its sphere and occasion. Only so far as this end is assumed as the true one do the difficulties encountered, the infinite exertions and annoyances made and endured for the attainment of the loved object, appear proportionate to the matter. For it is the future generation, in its whole individual determinateness, that presses into existence by means of those efforts and toils. Nay, it is itself already active in that careful, definite, and arbitrary

choice for the satisfaction of the sexual impulse which we call love. The growing inclination of two lovers is really already the will to live of the new individual which they can and desire to produce; nay, even in the meeting of their longing glances its new life breaks out, and announces itself as a future individuality harmoniously and well composed. They feel the longing for an actual union and fusing together into a single being, in order to live on only as this; and this longing receives its fulfilment in the child which is produced by them, as that in which the qualities transmitted by them both, fused and united in one being, live on. Conversely, the mutual, decided and persistent aversion between a man and a maid is a sign that what they could produce would only be a badly organised, in itself inharmonious and unhappy being. Hence there lies a deeper meaning in the fact that Calderon, though he calls the atrocious Semiramis the daughter of the air, yet introduces her as the daughter of rape followed by the murder of the husband.

But, finally, what draws two individuals of different sex exclusively to each other with such power is the will to live, which exhibits itself in the whole species, and which here anticipates in the individual which these two can produce an objectification of its nature answering to its aims. This individual will have the will, or character, from the father, the intellect from the mother, and the corporisation from both; yet, for the most part, the figure will take more after the father, the size after the mother, — according to the law which comes out in the breeding of hybrids among the brutes, and principally depends upon the fact that the size of the fœtus must conform to the size of the uterus. Just as inexplicable as the quite special individuality of any man, which is exclusively peculiar to him, is also the quite special and individual passion of two lovers; indeed at bottom the two are one and the same: the former is *explicite* what the latter was *implicite*. The moment at which the parents begin to love each other — to fancy each other, as the very happy English expression has it — is really to be regarded as the first appearance of a new individual and the true *punctum saliens* of its life, and, as has been said, in the meeting and fixing of their longing glances there appears the first germ of the new being, which certainly, like all germs, is generally crushed out. This new individual is to a certain extent a new (Platonic) Idea; and now, as all Ideas strive with the greatest vehemence to enter the phenomenal world, eagerly seizing for this end upon the matter which the law of causality divides among them all, so also does

this particular Idea of a human individuality strive with the greatest eagerness and vehemence towards its realisation in the phenomenon. This eagerness and vehemence is just the passion of the two future parents for each other. It has innumerable degrees, the two extremes of which may at any rate be described as Αφροδιτη πανδημος and ουρανια; in its nature, however, it is everywhere the same. On the other hand, it will be in degree so much the more powerful the more *individualised* it is; that is, the more the loved individual is exclusively suited, by virtue of all his or her parts and qualities, to satisfy the desire of the lover and the need established by his or her own individuality. What is really in question here will become clear in the further course of our exposition. Primarily and essentially the inclination of love is directed to health, strength, and beauty, consequently also to youth; because the will first of all seeks to exhibit the specific character of the human species as the basis of all individuality: ordinary amorousness (Αφροδιτη πανδημος) does not go much further. To these, then, more special claims link themselves on, which we shall investigate in detail further on, and with which, when they see satisfaction before them, the passion increases. But the highest degrees of this passion spring from that suitableness of two individualities to each other on account of which the will, *i.e.*, the character, of the father and the intellect of the mother, in their connection, make up precisely that individual towards which the will to live in general which exhibits itself in the whole species feels a longing proportionate to this its magnitude, and which therefore exceeds the measure of a mortal heart, and the motives of which, in the same way, lie beyond the sphere of the individual intellect. This is thus the soul of a true and great passion. Now the more perfect is the mutual adaptation of two individuals to each other in each of the many respects which have further to be considered, the stronger will be their mutual passion. Since there do not exist two individuals exactly alike, there must be for each particular man a particular woman — always with reference to what is to be produced — who corresponds most perfectly. A really passionate love is as rare as the accident of these two meeting. Since, however, the possibility of such a love is present in every one, the representations of it in the works of the poets are comprehensible to us. Just because the passion of love really turns about that which is to be produced, and its qualities, and because its kernel lies here, a friendship without any admixture of sexual love can exist between two young and good-looking persons of different sex, on account of the

agreement of their disposition, character, and mental tendencies; nay, as regards sexual love there may even be a certain aversion between them. The reason of this is to be sought in the fact that a child produced by them would have physical or mental qualities which were inharmonious; in short, its existence and nature would not answer the ends of the will to live as it exhibits itself in the species. On the other hand, in the case of difference of disposition, character, and mental tendency, and the dislike, nay, enmity, proceeding from this, sexual love may yet arise and exist; when it then blinds us to all that; and if it here leads to marriage it will be a very unhappy one.

Let us now set about the more thorough investigation of the matter. Egoism is so deeply rooted a quality of all individuals in general, that in order to rouse the activity of an individual being egoistical ends are the only ones upon which we can count with certainty. Certainly the species has an earlier, closer, and greater claim upon the individual than the perishable individuality itself. Yet when the individual has to act, and even make sacrifices for the continuance and quality of the species, the importance of the matter cannot be made so comprehensible to his intellect, which is calculated merely with regard to individual ends, as to have its proportionate effect. Therefore in such a case nature can only attain its ends by implanting a certain illusion in the individual, on account of which that which is only a good for the species appears to him as a good for himself, so that when he serves the species he imagines he is serving himself; in which process a mere chimera, which vanishes immediately afterwards, floats before him, and takes the place of a real thing as a motive. This illusion is instinct. In the great majority of cases this is to be regarded as the sense of the species, which presents what is of benefit to *it* to the will. Since, however, the will has here become individual, it must be so deluded that it apprehends through the sense of the individual what the sense of the species presents to it, thus imagines it is following individual ends while in truth it is pursuing ends which are merely general (taking this word in its strictest sense). The external phenomenon of instinct we can best observe in the brutes where its rôle is most important; but it is in ourselves alone that we arrive at a knowledge of its internal process, as of everything internal. Now it is certainly supposed that man has almost no instinct; at any rate only this, that the new-born babe seeks for and seizes the breast of its mother. But, in fact, we have a very definite, distinct, and complicated

instinct, that of the selection of another individual for the satisfaction of the sexual impulse, a selection which is so fine, so serious, and so arbitrary. With this satisfaction in itself, *i.e.*, so far as it is a sensual pleasure resting upon a pressing want of the individual, the beauty or ugliness of the other individual has nothing to do. Thus the regard for this which is yet pursued with such ardour, together with the careful selection which springs from it, is evidently connected, not with the chooser himself — although he imagines it is so — but with the true end, that which is to be produced, which is to receive the type of the species as purely and correctly as possible. Through a thousand physical accidents and moral aberrations there arise a great variety of deteriorations of the human form; yet its true type, in all its parts, is always again established: and this takes place under the guidance of the sense of beauty, which always directs the sexual impulse, and without which this sinks to the level of a disgusting necessity. Accordingly, in the first place, every one will decidedly prefer and eagerly desire the most beautiful individuals, *i.e.*, those in whom the character of the species is most purely impressed; but, secondly, each one will specially regard as beautiful in another individual those perfections which he himself lacks, nay, even those imperfections which are the opposite of his own. Hence, for example, little men love big women, fair persons like dark, &c. &c. The delusive ecstasy which seizes a man at the sight of a woman whose beauty is suited to him, and pictures to him a union with her as the highest good, is just the *sense of the species*, which, recognising the distinctly expressed stamp of the same, desires to perpetuate it with this individual. Upon this decided inclination to beauty depends the maintenance of the type of the species: hence it acts with such great power. We shall examine specially further on the considerations which it follows. Thus what guides man here is really an instinct which is directed to doing the best for the species, while the man himself imagines that he only seeks the heightening of his own pleasure. In fact, we have in this an instructive lesson concerning the inner nature of all instinct, which, as here, almost always sets the individual in motion for the good of the species. For clearly the pains with which an insect seeks out a particular flower, or fruit, or dung, or flesh, or, as in the case of the ichneumonidæ, the larva of another insect, in order to deposit its eggs there only, and to attain this end shrinks neither from trouble nor danger, is thoroughly analogous to the pains with which for his sexual satisfaction a man carefully chooses a woman with definite qualities

which appeal to him individually, and strives so eagerly after her that in order to attain this end he often sacrifices his own happiness in life, contrary to all reason, by a foolish marriage, by love affairs which cost him wealth, honour, and life, even by crimes such as adultery or rape, all merely in order to serve the species in the most efficient way, although at the cost of the individual, in accordance with the will of nature which is everywhere sovereign. Instinct, in fact, is always an act which seems to be in accordance with the conception of an end, and yet is entirely without such a conception. Nature implants it wherever the acting individual is incapable of understanding the end, or would be unwilling to pursue it. Therefore, as a rule, it is given only to the brutes, and indeed especially to the lowest of them which have least understanding; but almost only in the case we are here considering it is also given to man, who certainly could understand the end, but would not pursue it with the necessary ardour, that is, even at the expense of his individual welfare. Thus here, as in the case of all instinct, the truth assumes the form of an illusion, in order to act upon the will. It is a voluptuous illusion which leads the man to believe he will find a greater pleasure in the arms of a woman whose beauty appeals to him than in those of any other; or which indeed, exclusively directed to a single individual, firmly convinces him that the possession of her will ensure him excessive happiness. Therefore he imagines he is taking trouble and making sacrifices for his own pleasure, while he does so merely for the maintenance of the regular type of the species, or else a quite special individuality, which can only come from these parents, is to attain to existence. The character of instinct is here so perfectly present, thus an action which seems to be in accordance with the conception of an end, and yet is entirely without such a conception, that he who is drawn by that illusion often abhors the end which alone guides it, procreation, and would like to hinder it; thus it is in the case of almost all illicit love affairs. In accordance with the character of the matter which has been explained, every lover will experience a marvellous disillusion after the pleasure he has at last attained, and will wonder that what was so longingly desired accomplishes nothing more than every other sexual satisfaction; so that he does not see himself much benefited by it. That wish was related to all his other wishes as the species is related to the individual, thus as the infinite to the finite. The satisfaction, on the other hand, is really only for the benefit of the species, and thus does not come within the consciousness of the individual, who, inspired by the will of the

species, here served an end with every kind of sacrifice, which was not his own end at all. Hence, then, every lover, after the ultimate consummation of the great work, finds himself cheated; for the illusion has vanished by means of which the individual was here the dupe of the species, Accordingly Plato very happily says: “ἡδονη ἀπαντων αλαζονεστατον” (*voluptas ommlum maxime vaniloqua*), *Phileb.* 319.

But all this reflects light on the instincts and mechanical tendencies of the brutes. They also are, without doubt, involved in a kind of illusion, which deceives them with the prospect of their own pleasure, while they work so laboriously and with so much self-denial for the species, the bird builds its nest, the insect seeks the only suitable place for its eggs, or even hunts for prey which, unsuited for its own enjoyment, must be laid beside the eggs as food for the future larvæ, the bees, the wasps, the ants apply themselves to their skilful dwellings and highly complicated economy. They are all guided with certainty by an illusion, which conceals the service of the species under the mask of an egotistical end. This is probably the only way to comprehend the inner or subjective process that lies at the foundation of the manifestations of instinct. Outwardly, however, or objectively, we find in those creatures which are to a large extent governed by instinct, especially in insects, a preponderance of the ganglion system, *i.e.*, the *subjective* nervous system, over the objective or cerebral system; from which we must conclude that they are moved, not so much by objective, proper apprehension as by subjective ideas exciting desire, which arise from the influence of the ganglion system upon the brain, and accordingly by a kind of illusion; and this will be the *physiological* process in the case of all instinct. For the sake of illustration I will mention as another example of instinct in the human species, although a weak one, the capricious appetite of women who are pregnant. It seems to arise from the fact that the nourishment of the embryo sometimes requires a special or definite modification of the blood which flows to it, upon which the food which produces such a modification at once presents itself to the pregnant woman as an object of ardent longing, thus here also an illusion arises. Accordingly woman has one instinct more than man; and the ganglion system is also much more developed in the woman. That man has fewer instincts than the brutes and that even these few can be easily led astray, may be explained from the great preponderance of the brain in his case. The sense of beauty which instinctively guides the selection for the satisfaction

of sexual passion is led astray when it degenerates into the tendency to pederasty; analogous to the fact that the blue-bottle (*Musca vomitoria*), instead of depositing its eggs, according to instinct, in putrefying flesh, lays them in the blossom of the *Arum dracunculus*, deceived by the cadaverous smell of this plant.

Now that an instinct entirely directed to that which is to be produced lies at the foundation of all sexual love will receive complete confirmation from the fuller analysis of it, which we cannot therefore avoid. First of all we have to remark here that by nature man is inclined to inconstancy in love, woman to constancy. The love of the man sinks perceptibly from the moment it has obtained satisfaction; almost every other woman charms him more than the one he already possesses; he longs for variety. The love of the woman, on the other hand, increases just from that moment. This is a consequence of the aim of nature which is directed to the maintenance, and therefore to the greatest possible increase, of the species. The man can easily beget over a hundred children a year; the woman, on the contrary, with however many men, can yet only bring one child a year into the world (leaving twin births out of account). Therefore the man always looks about after other women; the woman, again, sticks firmly to the one man; for nature moves her, instinctively and without reflection, to retain the nourisher and protector of the future offspring. Accordingly faithfulness in marriage is with the man artificial, with the woman it is natural, and thus adultery on the part of the woman is much less pardonable than on the part of the man, both objectively on account of the consequences and also subjectively on account of its unnaturalness.

But in order to be thorough and gain full conviction that the pleasure in the other sex, however objective it may seem to us, is yet merely disguised instinct, *i.e.*, sense of the species, which strives to maintain its type, we must investigate more fully the considerations which guide us in this pleasure, and enter into the details of this, rarely as these details which will have to be mentioned here may have figured in a philosophical work before. These considerations divide themselves into those which directly concern the type of the species, *i.e.*, beauty, those which are concerned with physical qualities, and lastly, those which are merely relative, which arise from the requisite correction or neutralisation of the one-sided qualities and abnormities of the two individuals by each other. We shall go through them one by one.

The first consideration which guides our choice and inclination is age. In general we accept the age from the years when menstruation begins to those when it ceases, yet we give the decided preference to the period from the eighteenth to the twenty-eighth year. Outside of those years, on the other hand, no woman can attract us: an old woman, *i.e.*, one who no longer menstruates, excites our aversion. Youth without beauty has still always attraction; beauty without youth has none. Clearly the unconscious end which guides us here is the possibility of reproduction in general: therefore every individual loses attraction for the opposite sex in proportion as he or she is removed from the fittest period for begetting or conceiving. The second consideration is that of health. Acute diseases only temporarily disturb us, chronic diseases or cachexia repel us, because they are transmitted to the child. The third consideration is the skeleton, because it is the basis of the type of the species. Next to age and disease nothing repels us so much as a deformed figure; even the most beautiful face cannot atone for it; on the contrary, even the ugliest face when accompanied by a straight figure is unquestionably preferred. Further, we feel every disproportion of the skeleton most strongly; for example, a stunted, dumpy, short-boned figure, and many such; also a halting gait, where it is not the result of an extraneous accident. On the other hand, a strikingly beautiful figure can make up for all defects: it enchants us. Here also comes in the great value which all attach to the smallness of the feet: it depends upon the fact that they are an essential characteristic of the species, for no animal has the tarsus and the metatarsus taken together so small as man, which accords with his upright walk; he is a plantigrade. Accordingly Jesus Sirach also says (xxvi. 23, according to the revised translation by Kraus): "A woman with a straight figure and beautiful feet is like columns of gold in sockets of silver." The teeth also are important; because they are essential for nourishment and quite specially hereditary. The fourth consideration is a certain fulness of flesh; thus a predominance of the vegetative function, of plasticity; because this promises abundant nourishment for the fœtus; hence great leanness repels us in a striking degree. A full female bosom exerts an exceptional charm upon the male sex; because, standing in direct connection with the female functions of propagation, it promises abundant nourishment to the new-born child. On the other hand, excessively fat women excite our disgust: the cause is that this indicates atrophy of the uterus, thus barrenness; which is not known by the head, but by instinct.

The last consideration of all is the beauty of the face. Here also before everything else the bones are considered; therefore we look principally for a beautiful nose, and a short turned-up nose spoils everything. A slight inclination of the nose downwards or upwards has decided the happiness in life of innumerable maidens, and rightly so, for it concerns the type of the species. A small mouth, by means of small maxillæ, is very essential as specifically characteristic of the human countenance, as distinguished from the muzzle of the brutes. A receding or, as it were, cut-away chin is especially disagreeable, because *mentum prominulum* is an exclusive characteristic of our species. Finally comes the regard for beautiful eyes and forehead; it is connected with the psychical qualities, especially the intellectual which are inherited from the mother.

The unconscious considerations which, on the other hand, the inclination of women follows naturally cannot be so exactly assigned. In general the following may be asserted: They give the preference to the age from thirty to thirty-five years, especially over that of youths who yet really present the height of human beauty. The reason is that they are not guided by taste but by instinct, which recognises in the age named the acme of reproductive power. In general they look less to beauty, especially of the face. It is as if they took it upon themselves alone to impart this to the child. They are principally won by the strength of the man, and the courage which is connected with this; for these promise the production of stronger children, and also a brave protector for them. Every physical defect of the man, every divergence from the type, may with regard to the child be removed by the woman in reproduction, through the fact that she herself is blameless in these respects, or even exceeds in the opposite direction. Only those qualities of the man have to be excepted which are peculiar to his sex, and which therefore the mother cannot give to the child: such are the manly structure of the skeleton, broad shoulders, slender hips, straight bones, muscular power, courage, beard, &c. Hence it arises that women often love ugly men, but never an unmanly man, because they cannot neutralise his defects.

The second class of the considerations which lie at the foundation of sexual love are those which regard psychical qualities. Here we shall find that the woman is throughout attracted by the qualities of the heart or character in the man, as those which are inherited from the father. The woman is won especially by firmness of will, decision, and courage, and

perhaps also by honesty and good-heartedness. On the other hand, intellectual gifts exercise no direct and instinctive power over her, just because they are not inherited from the father. Want of understanding does a man no harm with women; indeed extraordinary mental endowment, or even genius, might sooner influence them unfavourably as an abnormity. Hence one often sees an ugly, stupid, and coarse fellow get the better of a cultured, able, and amiable man with women. Also marriages from love are sometimes consummated between natures which are mentally very different: for example, the man is rough, powerful, and stupid; the woman tenderly sensitive, delicately thoughtful, cultured, æsthetic, &c.; or the man is a genius and learned, the woman a goose:

"*Sic visum Veneri; cui placet impares*
Formas atque animos sub juga aënea
Sævo mittere cum joco."

The reason is, that here quite other considerations than the intellectual predominate, — those of instinct. In marriage what is looked to is not intellectual entertainment, but the production of children: it is a bond of the heart, not of the head. It is a vain and absurd pretence when women assert that they have fallen in love with the mind of a man, or else it is the over-straining of a degenerate nature. Men, on the other hand, are not determined in their instinctive love by the qualities of character of the woman; hence so many Socrateses have found their Xantippes; for example, Shakspeare, Albrecht Dürer, Byron, &c. The intellectual qualities, however, certainly influence here, because they are inherited from the mother. Yet their influence is easily outweighed by that of physical beauty, which acts directly, as concerning a more essential point. However, it happens, either from the feeling or the experience of that influence, that mothers have their daughters taught the fine arts, languages, and so forth in order to make them attractive to men, whereby they wish to assist the intellect by artificial means, just as, in case of need, they assist the hips and the bosom. Observe that here we are speaking throughout only of that entirely immediate instinctive attraction from which alone love properly so called grows. That a woman of culture and understanding prizes understanding and intellect in a man, that a man from rational reflection should test and have regard to the character of his bride, has nothing to do with the matter with which we are dealing here. Such things lie at the bottom of a rational choice in marriage, but not of the passionate love, which is our theme.

Hitherto I have only taken account of the *absolute* considerations, *i.e.*, those which hold good for every one: I come now to the *relative* considerations, which are individual, because in their case what is looked to is the rectification of the type of the species, which is already defectively presented, the correction of the divergences from it which the chooser's own person already bears in itself, and thus the return to the pure presentation of the type. Here, then, each one loves what he lacks. Starting from the individual constitution, and directed to the individual constitution, the choice which rests upon such relative considerations is much more definite, decided, and exclusive than that which proceeds merely from the absolute considerations; therefore the source of really passionate love will lie, as a rule, in these relative considerations, and only that of the ordinary and slighter inclination in the absolute considerations. Accordingly it is not generally precisely correct and perfect beauties that kindle great passions. For such a truly passionate inclination to arise something is required which can only be expressed by a chemical metaphor: two persons must neutralise each other, like acid and alkali, to a neutral salt. The essential conditions demanded for this are the following. First: all sex is one-sided. This one-sidedness is more distinctly expressed in one individual than in another; therefore in every individual it can be better supplemented and neutralised by one than by another individual of the opposite sex, for each one requires a one-sidedness which is the opposite of his own to complete the type of humanity in the new individual that is to be produced, the constitution of which is always the goal towards which all tends. Physiologists know that manhood and womanhood admit of innumerable degrees, through which the former sinks to the repulsive gynander and hypospadæus, and the latter rises to the graceful androgyne; from both sides complete hermaphrodism can be reached, at which point stand those individuals who, holding the exact mean between the two sexes, can be attributed to neither, and consequently are unfit to propagate the species. Accordingly, the neutralisation of two individualities by each other, of which we are speaking, demands that the definite degree of *his* manhood shall exactly correspond to the definite degree of *her* womanhood; so that the one-sidedness of each exactly annuls that of the other. Accordingly, the most manly man will seek the most womanly woman, and *vice versâ*, and in the same way every individual will seek another corresponding to him or her in degree of sex. Now how far the required relation exists between two individuals is instinctively felt by

them, and, together with the other relative considerations, lies at the foundation of the higher degrees of love. While, therefore, the lovers speak pathetically of the harmony of their souls, the heart of the matter is for the most part the agreement or suitableness pointed out here with reference to the being which is to be produced and its perfection, and which is also clearly of much more importance than the harmony of their souls, which often, not long after the marriage, resolves itself into a howling discord. Now, here come in the further relative considerations, which depend upon the fact that every one endeavours to neutralise by means of the other his weaknesses, defects, and deviations from the type, so that they will not perpetuate themselves, or even develop into complete abnormities in the child which is to be produced. The weaker a man is as regards muscular power the more will he seek for strong women; and the woman on her side will do the same. But since now a less degree of muscular power is natural and regular in the woman, women as a rule will give the preference to strong men. Further, the size is an important consideration. Little men have a decided inclination for big women, and *vice versâ*; and indeed in a little man the preference for big women will be so much the more passionate if he himself was begotten by a big father, and only remains little through the influence of his mother; because he has inherited from his father the vascular system and its energy, which was able to supply a large body with blood. If, on the other hand, his father and grandfather were both little, that inclination will make itself less felt. At the foundation of the aversion of a big woman to big men lies the intention of nature to avoid too big a race, if with the strength which *this* woman could impart to them they would be too weak to live long. If, however, such a woman selects a big husband, perhaps for the sake of being more presentable in society, then, as a rule, her offspring will have to atone for her folly. Further, the consideration as to the complexion is very decided. Blondes prefer dark persons, or brunettes; but the latter seldom prefer the former. The reason is, that fair hair and blue eyes are in themselves a variation from the type, almost an abnormity, analogous to white mice, or at least to grey horses. In no part of the world, not even in the vicinity of the pole, are they indigenous, except in Europe, and are clearly of Scandinavian origin. I may here express my opinion in passing that the white colour of the skin is not natural to man, but that by nature he has a black or brown skin, like our forefathers the Hindus; that consequently a white man has never originally sprung from the womb of

nature, and that thus there is no such thing as a white race, much as this is talked of, but every white man is a faded or bleached one. Forced into the strange world, where he only exists like an exotic plant, and like this requires in winter the hothouse, in the course of thousands of years man became white. The gipsies, an Indian race which immigrated only about four centuries ago, show the transition from the complexion of the Hindu to our own.[38] Therefore in sexual love nature strives to return to dark hair and brown eyes as the primitive type; but the white colour of the skin has become a second nature, though not so that the brown of the Hindu repels us. Finally, each one also seeks in the particular parts of the body the corrective of his own defects and aberrations, and does so the more decidedly the more important the part is. Therefore snub-nosed individuals have an inexpressible liking for hook-noses, parrot-faces; and it is the same with regard to all other parts. Men with excessively slim, long bodies and limbs can find beauty in a body which is even beyond measure stumpy and short. The considerations with regard to temperament act in an analogous manner. Each will prefer the temperament opposed to his own; yet only in proportion as his one is decided. Whoever is himself in some respect very perfect does not indeed seek and love imperfection in this respect, but is yet more easily reconciled to it than others; because he himself insures the children against great imperfection of this part. For example, whoever is himself very white will not object to a yellow complexion; but whoever has the latter will find dazzling whiteness divinely beautiful. The rare case in which a man falls in love with a decidedly ugly woman occurs when, besides the exact harmony of the degree of sex explained above, the whole of her abnormities are precisely the opposite, and thus the corrective, of his. The love is then wont to reach a high degree.

The profound seriousness with which we consider and ponder each bodily part of the woman, and she on her part does the same, the critical scrupulosity with which we inspect a woman who begins to please us, the capriciousness of our choice, the keen attention with which the bridegroom observes his betrothed, his carefulness not to be deceived in any part, and the great value which he attaches to every excess or defect in the essential parts, all this is quite in keeping with the importance of the end. For the new being to be produced will have to bear through its whole life a similar part. For example, if the woman is only a little crooked, this may easily impart to her son a hump, and so in all the rest. Consciousness of all this certainly

does not exist. On the contrary, every one imagines that he makes that careful selection in the interest of his own pleasure (which at bottom cannot be interested in it at all); but he makes it precisely as, under the presupposition of his own corporisation, is most in keeping with the interest of the species, to maintain the type of which as pure as possible is the secret task. The individual acts here, without knowing it, by order of something higher than itself, the species; hence the importance which it attaches to things which may and indeed must be, indifferent to itself as such. There is something quite peculiar in the profound unconscious seriousness with which two young persons of opposite sex who see each other for the first time regard each other, in the searching and penetrating glance they cast at one another, in the careful review which all the features and parts of their respective persons have to endure. This investigating and examining is the *meditation of the genius of the species* on the individual which is possible through these two and the combination of its qualities. According to the result of this meditation is the degree of their pleasure in each other and their yearning for each other. This yearning, even after it has attained a considerable degree, may be suddenly extinguished again by the discovery of something that had previously remained unobserved. In this way, then, the genius of the species meditates concerning the coming race in all who are capable of reproduction. The nature of this race is the great work with which Cupid is occupied, unceasingly active, speculating, and pondering. In comparison with the importance of his great affair, which concerns the species and all coming races, the affairs of individuals in their whole ephemeral totality are very trifling; therefore he is always ready to sacrifice these regardlessly. For he is related to them as an immortal to mortals, and his interests to theirs as infinite to finite. Thus, in the consciousness of managing affairs of a higher kind than all those which only concern individual weal or woe, he carries them on sublimely, undisturbed in the midst of the tumult of war, or in the bustle of business life, or during the raging of a plague, and pursues them even into the seclusion of the cloister.

We have seen in the above that the intensity of love increases with its individualisation, because we have shown that the physical qualities of two individuals can be such that, for the purpose of restoring as far as possible the type of the species, the one is quite specially and perfectly the completion or supplement of the other, which therefore desires it exclusively. Already in this case a considerable passion arises, which at

once gains a nobler and more sublime appearance from the fact that it is directed to an individual object, and to it alone; thus, as it were, arises at the special order of the species. For the opposite reason, the mere sexual impulse is ignoble, because without individualisation it is directed to all, and strives to maintain the species only as regards quantity, with little respect to quality. But the individualising, and with it the intensity of the love, can reach so high a degree that without its satisfaction all the good things in the world, and even life itself, lose their value. It is then a wish which attains a vehemence that no other wish ever reaches, and therefore makes one ready for any sacrifice, and in case its fulfilment remains unalterably denied, may lead to madness or suicide. At the foundation of such an excessive passion there must lie, besides the considerations we have shown above, still others which we have not thus before our eyes. We must therefore assume that here not only the corporisation, but the *will* of the man and the *intellect* of the woman are specially suitable to each other, in consequence of which a perfectly definite individual can be produced by them alone, whose existence the genius of the species has here in view, for reasons which are inaccessible to us, since they lie in the nature of the thing in itself. Or, to speak more exactly, the will to live desires here to objectify itself in a perfectly definite individual, which can only be produced by this father with this mother. This metaphysical desire of the will in itself has primarily no other sphere of action in the series of existences than the hearts of the future parents, which accordingly are seized with this ardent longing, and now imagine themselves to desire on their own account what really for the present has only a purely metaphysical end, *i.e.*, an end which lies outside the series of actually existing things. Thus it is the ardent longing to enter existence of the future individual which has first become possible here, a longing which proceeds from the primary source of all being, and exhibits itself in the phenomenal world as the lofty passion of the future parents for each other, paying little regard to all that is outside itself; in fact, as an unparalleled illusion, on account of which such a lover would give up all the good things of this world to enjoy the possession of this woman, who yet can really give him nothing more than any other. That yet it is just this possession that is kept in view here is seen from the fact that even this lofty passion, like all others, is extinguished in its enjoyment — to the great astonishment of those who are possessed by it. It also becomes extinct when, through the woman turning out barren (which, according to

Hufeland, may arise from nineteen accidental constitutional defects), the real metaphysical end is frustrated; just as daily happens in millions of germs trampled under foot, in which yet the same metaphysical life principle strives for existence; for which there is no other consolation than that an infinity of space, time, and matter, and consequently inexhaustible opportunity for return, stands open to the will to live.

The view which is here expounded must once have been present to the mind of Theophrastus Paracelsus, even if only in a fleeting form, though he has not handled this subject, and my whole system of thought was foreign to him; for, in quite a different context and in his desultory manner, he wrote the following remarkable words: "*Hi sunt, quos Deus copulavit, ut eam, quæ fuit Uriæ et David; quamvis ex diametro (sic enim sibi humana mens persuadebat) cum justo et legitimo matrimonio pugnaret hoc.... sed propter Salomonem*, qui aliunde nasci non potuit, *nisi ex Bathseba, conjuncto David semine, quamvis meretrice, conjunxit eos Deus*" (*De vita longa*, i. 5).

The longing of love, the ἵμερος, which the poets of all ages are unceasingly occupied with expressing in innumerable forms, and do not exhaust the subject, nay, cannot do it justice, this longing, which attaches the idea of endless happiness to the possession of a particular woman, and unutterable pain to the thought that this possession cannot be attained, — this longing and this pain cannot obtain their material from the wants of an ephemeral individual; but they are the sighs of the spirit of the species, which sees here, to be won or lost, a means for the attainment of its ends which cannot be replaced, and therefore groans deeply. The species alone has infinite life, and therefore is capable of infinite desires, infinite satisfaction, and infinite pain. But these are here imprisoned in the narrow breast of a mortal. No wonder, then, if such a breast seems like to burst, and can find no expression for the intimations of infinite rapture or infinite misery with which it is filled. This, then, affords the materials for all erotic poetry of a sublime kind, which accordingly rises into transcendent metaphors, soaring above all that is earthly. This is the theme of Petrarch, the material for the St. Preuxs, Werthers, and Jacopo Ortis, who apart from it could not be understood nor explained. For that infinite esteem for the loved one cannot rest upon some spiritual excellences, or in general upon any objective, real qualities of hers; for one thing, because she is often not sufficiently well known to the lover, as was the case with Petrarch. The

spirit of the species alone can see at one glance what *worth* she has for *it*, for its ends. And great passions also arise, as a rule, at the first glance:

"Who ever loved that loved not at first sight?"

— Shakspeare, "As You Like it," iii. 5.

In this regard a passage in the romance of "*Guzman de Alfarache*," by Mateo Aleman, which has been famous for 250 years, is remarkable: "*No es necessario, para que uno ame, que pase distancia de tiempo, que siga discurso, ni haga eleccion, sino que con aquella primera y sola vista, concurran juntamente cierta correspondencia ó consonancia, ó lo que acá solemos vulgarmente decir, una confrontacion de sangre, a que por particular influxo suelen mover las estrellas.*" (For one to love it is not necessary that much time should pass, that he should set about reflecting and make a choice; but only that at that first and only glance a certain correspondence and consonance should be encountered on both sides, or that which in common life we are wont to call a *sympathy of the blood*, and to which a special influence of the stars generally impels), P. ii. lib. iii. c. 5. Accordingly the loss of the loved one, through a rival, or through death, is also for the passionate lover a pain that surpasses all others, just because it is of a transcendental kind, since it affects him not merely as an individual, but attacks him in his *essentia æterna*, in the life of the species into whose special will and service he was here called. Hence jealousy is such torment and so grim, and the surrender of the loved one is the greatest of all sacrifices. A hero is ashamed of all lamentations except the lamentation of love, because in this it is not he but the species that laments. In Calderon's "Zenobia the Great" there is in the first act a scene between Zenobia and Decius in which the latter says:

"*Cielos, luego tu me quieres? Perdiera cien mil victorias, Volviérame,*" &c.

(Heaven! then thou lovest me? For this I would lose a thousand victories, would turn about, &c.)

Here, honour, which hitherto outweighed every interest, is beaten out of the field as soon as sexual love, *i.e.*, the interest of the species, comes into play, and sees before it a decided advantage; for this is infinitely superior to every interest of mere individuals, however important it may be. Therefore to this alone honour, duty, and fidelity yield after they have withstood every other temptation, including the threat of death. In the same way we find in private life that conscientiousness is in no point so rare as in this: it is here

sometimes set aside even by persons who are otherwise honest and just, and adultery is recklessly committed when passionate love, *i.e.*, the interest of the species, has mastered them. It even seems as if in this they believed themselves to be conscious of a higher right than the interests of individuals can ever confer; just because they act in the interest of the species. In this reference Chamfort's remark is worth noticing: "*Quand un homme et une femme ont l'un pour l'autre une passion violente, il me semble toujours que quelque soient les obstacles qui les séparent, un mari, des parens, etc., les deux amans sont l'un a l'autre, de par la Nature, qu'ils s'appartiennent de droit divin, malgré les lois et les conventions humaines*." Whoever is inclined to be incensed at this should be referred to the remarkable indulgence which the Saviour shows in the Gospel to the woman taken in adultery, in that He also assumes the same guilt in the case of all present. From this point of view the greater part of the "Decameron" appears as mere mocking and jeering of the genius of the species at the rights and interests of individuals which it tramples under foot. Differences of rank and all similar circumstances, when they oppose the union of passionate lovers, are set aside with the same ease and treated as nothing by the genius of the species, which, pursuing its ends that concern innumerable generations, blows off as spray such human laws and scruples. From the same deep-lying grounds, when the ends of passionate love are concerned, every danger is willingly encountered, and those who are otherwise timorous here become courageous. In plays and novels also we see, with ready sympathy, the young persons who are fighting the battle of their love, *i.e.*, the interest of the species, gain the victory over their elders, who are thinking only of the welfare of the individuals. For the efforts of the lovers appear to us as much more important, sublime, and therefore right, than anything that can be opposed to them, as the species is more important than the individual. Accordingly the fundamental theme of almost all comedies is the appearance of the genius of the species with its aims, which are opposed to the personal interest of the individuals presented, and therefore threaten to undermine their happiness. As a rule it attains its end, which, as in accordance with poetical justice, satisfies the spectator, because he feels that the aims of the species are much to be preferred to those of the individual. Therefore at the conclusion he leaves the victorious lovers quite confidently, because he shares with them the illusion that they have founded their own happiness, while they have rather sacrificed it to the choice of the

species, against the will and foresight of their elders. It has been attempted in single, abnormal comedies to reverse the matter and bring about the happiness of the individuals at the cost of the aims of the species; but then the spectator feels the pain which the genius of the species suffers, and is not consoled by the advantages which are thereby assured to the individuals. As examples of this kind two very well-known little pieces occur to me: "*La reine de 16 ans*," and "*Le marriage de raison*." In tragedies containing love affairs, since the aims of the species are frustrated, the lovers who were its tools, generally perish also; for example, in "Romeo and Juliet," "Tancred," "Don Carlos," "Wallenstein," "The Bride of Messina," and many others.

The love of a man often affords comical, and sometimes also tragical phenomena; both because, taken possession of by the spirit of the species, he is now ruled by this, and no longer belongs to himself: his conduct thereby becomes unsuited to the individual. That which in the higher grades of love imparts such a tinge of poetry and sublimeness to his thoughts, which gives them even a transcendental and hyperphysical tendency, on account of which he seems to lose sight altogether of his real, very physical aim, is at bottom this, that he is now inspired by the spirit of the species whose affairs are infinitely more important than all those which concern mere individuals, in order to find under the special directions of this spirit the whole existence of an indefinitely long posterity with this individual and exactly determined nature, which it can receive only from him as father and the woman he loves as mother, and which otherwise could never, *as such*, attain to existence, while the objectification of the will to live expressly demands this existence. It is the feeling that he is acting in affairs of such transcendent importance which raises the lover so high above everything earthly, nay, even above himself, and gives such a hyperphysical clothing to his very physical desires, that love becomes a poetical episode even in the life of the most prosaic man; in which last case the matter sometimes assumes a comical aspect. That mandate of the will which objectifies itself in the species exhibits itself in the consciousness of the lover under the mask of the anticipation of an infinite blessedness which is to be found for him in the union with this female individual. Now, in the highest grades of love this chimera becomes so radiant that if it cannot be attained life itself loses all charm, and now appears so joyless, hollow, and insupportable that the disgust at it even overcomes the fear of death, so that it is then

sometimes voluntarily cut short. The will of such a man has been caught in the vortex of the will of the species, or this has obtained such a great predominance over the individual will that if such a man cannot be effective in the first capacity, he disdains to be so in the last. The individual is here too weak a vessel to be capable of enduring the infinite longing of the will of the species concentrated upon a definite object. In this case, therefore, the issue is suicide, sometimes the double suicide of the two lovers; unless, to save life, nature allows madness to intervene, which then covers with its veil the consciousness of that hopeless state. No year passes without proving the reality of what has been expounded by several cases of all these kinds.

Not only, however, has the unsatisfied passion of love sometimes a tragic issue, but the satisfied passion also leads oftener to unhappiness than to happiness. For its demands often conflict so much with the personal welfare of him who is concerned that they undermine it, because they are incompatible with his other circumstances, and disturb the plan of life built upon them. Nay, not only with external circumstances is love often in contradiction, but even with the lover's own individuality, for it flings itself upon persons who, apart from the sexual relation, would be hateful, contemptible, and even abhorrent to the lover. But so much more powerful is the will of the species than that of the individual that the lover shuts his eyes to all those qualities which are repellent to him, overlooks all, ignores all, and binds himself for ever to the object of his passion — so entirely is he blinded by that illusion, which vanishes as soon as the will of the species is satisfied, and leaves behind a detested companion for life. Only from this can it be explained that we often see very reasonable and excellent men bound to termagants and she-devils, and cannot conceive how they could have made such a choice. On this account the ancients represented love as blind. Indeed, a lover may even know distinctly and feel bitterly the faults of temperament and character of his bride, which promise him a miserable life, and yet not be frightened away: —

"I ask not, I care not,
If guilt's in thy heart,
I know that I love thee
Whatever thou art."

For ultimately he seeks not his own things, but those of a third person, who has yet to come into being, although he is involved in the illusion that

what he seeks is his own affair. But it is just this not seeking of one's own things which is everywhere the stamp of greatness, that gives to passionate love also a touch of sublimity, and makes it a worthy subject of poetry. Finally, sexual love is compatible even with the extremest hatred towards its object: therefore Plato has compared it to the love of the wolf for the sheep. This case appears when a passionate lover, in spite of all efforts and entreaties, cannot obtain a favourable hearing on any condition: —

"I love and hate her."

— Shakspeare, *Cymb.*, iii. 5.

The hatred of the loved one which then is kindled sometimes goes so far that the lover murders her, and then himself. One or two examples of this generally happen every year; they will be found in the newspapers. Therefore Goethe's lines are quite correct: —

"By all despised love! By hellish element!

Would that I knew a worse, that I might swear by!"

It is really no hyperbole if a lover describes the coldness of his beloved and the delight of her vanity, which feeds on his sufferings, as cruelty; for he is under the influence of an impulse which, akin to the instinct of insects, compels him, in spite of all grounds of reason, to pursue his end unconditionally, and to undervalue everything else: he cannot give it up. Not one but many a Petrarch has there been who was compelled to drag through life the unsatisfied ardour of love, like a fetter, an iron weight at his foot, and breathe his sighs in lonely woods; but only in the one Petrarch dwelt also the gift of poetry; so that Goethe's beautiful lines hold good of him: —

"And when in misery the man was dumb

A god gave me the power to tell my sorrow."

In fact, the genius of the species wages war throughout with the guardian geniuses of individuals, is their pursuer and enemy, always ready relentlessly to destroy personal happiness in order to carry out its ends; nay, the welfare of whole nations has sometimes been sacrificed to its humours. An example of this is given us by Shakspeare in "Henry VI.," pt. iii., act 3, sc. 2 and 3. All this depends upon the fact that the species, as that in which the root of our being lies, has a closer and earlier right to us than the individual; hence its affairs take precedence. From the feeling of this the ancients personified the genius of the species in Cupid, a malevolent, cruel,

and therefore ill-reputed god, in spite of his childish appearance; a capricious, despotic demon, but yet lord of gods and men:

"Συ δ᾽ω θεων τυραννε κ᾽ανθρωπων, Ερως!"

(*Tu, deorum hominumque tyranne, Amor!*)

A deadly shot, blindness, and wings are his attributes. The latter signify inconstancy; and this appears, as a rule, only with the disillusion which is the consequence of satisfaction.

Because the passion depended upon an illusion, which represented that which has only value for the species as valuable for the individual, the deception must vanish after the attainment of the end of the species. The spirit of the species which took possession of the individual sets it free again. Forsaken by this spirit, the individual falls back into its original limitation and narrowness, and sees with wonder that after such a high, heroic, and infinite effort nothing has resulted for its pleasure but what every sexual gratification affords. Contrary to expectation, it finds itself no happier than before. It observes that it has been the dupe of the will of the species. Therefore, as a rule, a Theseus who has been made happy will forsake his Ariadne. If Petrarch's passion had been satisfied, his song would have been silenced from that time forth, like that of the bird as soon as the eggs are laid.

Here let me remark in passing that however much my metaphysics of love will displease the very persons who are entangled in this passion, yet if rational considerations in general could avail anything against it, the fundamental truth disclosed by me would necessarily fit one more than anything else to subdue it. But the saying of the old comedian will, no doubt, remain true: "*Quæ res in se neque consilium, neque modum habet ullum, eam consilio regere non potes.*"

Marriages from love are made in the interest of the species, not of the individuals. Certainly the persons concerned imagine they are advancing their own happiness; but their real end is one which is foreign to themselves, for it lies in the production of an individual which is only possible through them. Brought together by this aim, they ought henceforth to try to get on together as well as possible. But very often the pair brought together by that instinctive illusion, which is the essence of passionate love, will, in other respects, be of very different natures. This comes to light when the illusion vanishes, as it necessarily must. Accordingly love marriages, as a rule, turn out unhappy; for through them the coming

generation is cared for at the expense of the present. “*Quien se casa por amores, ha de vivir con dolores*” (Who marries from love must live in sorrow), says the Spanish proverb. The opposite is the case with marriages contracted for purposes of convenience, generally in accordance with the choice of the parents. The considerations prevailing here, of whatever kind they may be, are at least real, and cannot vanish of themselves. Through them, however, the happiness of the present generation is certainly cared for, to the disadvantage of the coming generation, and notwithstanding this it remains problematical. The man who in his marriage looks to money more than to the satisfaction of his inclination lives more in the individual than in the species; which is directly opposed to the truth; hence it appears unnatural, and excites a certain contempt. A girl who, against the advice of her parents, rejects the offer of a rich and not yet old man, in order, setting aside all considerations of convenience, to choose according to her instinctive inclination alone, sacrifices her individual welfare to the species. But just on this account one cannot withhold from her a certain approbation; for she has preferred what is of most importance, and has acted in the spirit of nature (more exactly, of the species), while the parents advised in the spirit of individual egoism. In accordance with all this, it appears as if in making a marriage either the individual or the interests of the species must come off a loser. And this is generally the case; for that convenience and passionate love should go hand in hand is the rarest of lucky accidents. The physical, moral, or intellectual deficiency of the nature of most men may to some extent have its ground in the fact that marriages are ordinarily entered into not from pure choice and inclination, but from all kinds of external considerations, and on account of accidental circumstances. If, however, besides convenience, inclination is also to a certain extent regarded, this is, as it were, an agreement with the genius of the species. Happy marriages are well known to be rare; just because it lies in the nature of marriage that its chief end is not the present but the coming generation. However, let me add, for the consolation of tender, loving natures, that sometimes passionate sexual love associates itself with a feeling of an entirely different origin — real friendship based upon agreement of disposition, which yet for the most part only appears when sexual love proper is extinguished in its satisfaction. This friendship will then generally spring from the fact that the supplementing and corresponding physical, moral, and intellectual qualities of the two individuals, from which sexual love arose, with reference to the

child to be produced, are, with reference also to the individuals themselves, related to each other in a supplementary manner as opposite qualities of temperament and mental gifts, and thereby form the basis of a harmony of disposition.

The whole metaphysics of love here dealt with stands in close connection with my metaphysics in general, and the light which it throws upon this may be summed up as follows.

We have seen that the careful selection for the satisfaction of the sexual impulse, a selection which rises through innumerable degrees up to that of passionate love, depends upon the highly serious interest which man takes in the special personal constitution of the next generation. Now this exceedingly remarkable interest confirms two truths which have been set forth in the preceding chapters. (1.) The indestructibility of the true nature of man, which lives on in that coming generation. For that interest which is so lively and eager, and does not spring from reflection and intention, but from the inmost characteristics and tendencies of our nature, could not be so indelibly present and exercise such great power over man if he were absolutely perishable, and were merely followed in time by a race actually and entirely different from him. (2.) That his true nature lies more in the species than in the individual. For that interest in the special nature of the species, which is the root of all love, from the passing inclination to the serious passion, is for every one really the highest concern, the success or failure of which touches him most sensibly; therefore it is called *par excellence* the affair of the heart. Moreover, when this interest has expressed itself strongly and decidedly, everything which merely concerns one's own person is postponed and necessarily sacrificed to it. Through this, then, man shows that the species lies closer to him than the individual, and he lives more immediately in the former than in the latter. Why does the lover hang with complete abandonment on the eyes of his chosen one, and is ready to make every sacrifice for her? Because it is his immortal part that longs after her; while it is only his mortal part that desires everything else. That vehement or intense longing directed to a particular woman is accordingly an immediate pledge of the indestructibility of the kernel of our being, and of its continued existence in the species. But to regard this continued existence as something trifling and insufficient is an error which arises from the fact that under the conception of the continued life of the species one thinks nothing more than the future existence of beings similar

to us, but in no regard identical with us; and this again because, starting from knowledge directed towards without, one takes into consideration only the external form of the species as we apprehend it in perception, and not its inner nature. But it is just this inner nature which lies at the foundation of our own consciousness as its kernel, and hence indeed is more immediate than this itself, and, as thing in itself, free from the *principium individuationis*, is really the same and identical in all individuals, whether they exist together or after each other. Now this is the will to live, thus just that which desires life and continuance so vehemently. This accordingly is spared and unaffected by death. It can attain to no better state than its present one; and consequently for it, with life, the constant suffering and striving of the individuals is certain. To free it from this is reserved for the denial of the will to live, as the means by which the individual will breaks away from the stem of the species, and surrenders that existence in it. We lack conceptions for that which it now is; indeed all data for such conceptions are wanting. We can only describe it as that which is free to be will to live or not. Buddhism denotes the latter case by the word Nirvana, the etymology of which was given in the note at the end of chapter 41. It is the point which remains for ever unattainable to all human knowledge, just as such.

If now, from the standpoint of this last consideration, we contemplate the turmoil of life, we behold all occupied with its want and misery, straining all their powers to satisfy its infinite needs and to ward off its multifarious sorrows, yet without daring to hope anything else than simply the preservation of this tormented existence for a short span of time. In between, however, in the midst of the tumult, we see the glances of two lovers meet longingly: yet why so secretly, fearfully, and stealthily? Because these lovers are the traitors who seek to perpetuate the whole want and drudgery, which would otherwise speedily reach an end; this they wish to frustrate, as others like them have frustrated it before. This consideration already passes over into the subject of the following chapter.[39]

Chapter XLV.[40] On The Assertion Of The Will To Live.

If the will to live exhibited itself merely as an impulse to self-preservation, this would only be an assertion of the individual phenomenon for the span of time of its natural duration. The cares and troubles of such a life would not be great, and consequently existence would be easy and serene. Since, on the contrary, the will wills life absolutely and for all time, it exhibits itself also as sexual impulse, which has in view an endless series of generations. This impulse does away with that carelessness, serenity, and innocence which would accompany a merely individual existence, for it brings unrest and melancholy into the consciousness; misfortunes, cares, and misery into the course of life. If, on the other hand, it is voluntarily suppressed, as we see in rare exceptions, then this is the turning of the will, which changes its course. The will does not then transcend the individual, but is abolished in it. Yet this can only take place by means of the individual doing painful violence to itself. If, however, it does take place, then the freedom from care and the serenity of the purely individual existence is restored to the consciousness, and indeed in a higher degree. On the other hand, to the satisfaction of that most vehement of all impulses and desires is linked the origin of a new existence, thus the carrying out of life anew, with all its burdens, cares, wants, and pains; certainly in another individual; yet if the two who are different in the phenomenon were so absolutely and in themselves, where would then be eternal justice? Life presents itself as a problem, a task to be worked out, and therefore, as a rule, as a constant conflict with necessity. Accordingly every one tries to get through with it and come off as well as he can. He performs life as a compulsory service which he owes. But who has contracted the debt? — His begetter, in the enjoyment of sensual pleasure. Thus, because the one has enjoyed this, the other must live, suffer, and die. However, we know and look back here to the fact that the difference of the similar is conditioned by space and time, which in this sense I have called the *principium individuationis*. Otherwise eternal justice could not be vindicated. Paternal love, on account of which the father is ready to do, to suffer, and to risk more for his child than for himself, and at the same time knows that he owes this, depends simply upon the fact that the begetter recognises himself in the begotten.

The life of a man, with its endless care, want, and suffering, is to be regarded as the explanation and paraphrase of the act of procreation, *i.e.*, the decided assertion of the will to live; and further, it is also due to this that he owes to nature the debt of death, and thinks with anxiety of this debt. Is this not evidence of the fact that our existence involves guilt? At any rate, we always exist, subject to the periodical payment of the toll, birth and death, and successively partake of all the sorrows and joys of life, so that none can escape us: this is just the fruit of the assertion of the will to live. Thus the fear of death, which in spite of all the miseries of life holds us firmly to it, is really illusory; but just as illusory is the impulse which has enticed us into it. This enticement itself may be seen objectively in the reciprocal longing glances of two lovers; they are the purest expression of the will to live, in its assertion. How soft and tender it is here! It wills well-being, and quiet pleasure, and mild joys for itself, for others, for all. It is the theme of Anacreon. Thus by allurements and flattery it makes its way into life. But when once it is there, misery introduces crime, and crime misery; horror and desolation fill the scene. It is the theme of Æschylus.

But now the act through which the will asserts itself and man arises is one of which all are, in their inmost being, ashamed, which they therefore carefully conceal; nay, if they are caught in it, are terrified as if they had been taken in a crime. It is an action of which in cold reflection one generally thinks with dislike, and in a lofty mood with loathing. Reflections which in this regard approach the matter more closely are offered by Montaigne in the fifth chapter of the third book, under the marginal heading: "*Ce que c'est que l'amour*." A peculiar sadness and repentance follows close upon it, is yet most perceptible after the first performance of the act, and in general is the more distinct the nobler is the character. Hence even Pliny, the pagan, says: "*Homini tantum primi coitus pœnitentia, augurium scilicet vitæ, a pœnitenda origine*" (*Hist. Nat.*, x. 83). And, on the other hand, in Goethe's "Faust," what do devil and witches practise and sing of on their Sabbath? Lewdness and obscenity. And in the same work (in the admirable "Paralipomena" to "Faust") what does incarnate Satan preach before the assembled multitude? Lewdness and obscenity. But simply and solely by means of the continual practice of such an act as this does the human race subsist. If now optimism were right, if our existence were to be thankfully recognised as the gift of the highest goodness guided by wisdom, and accordingly in itself praiseworthy, commendable, and agreeable, then

certainly the act which perpetuates it would necessarily have borne quite another physiognomy. If, on the other hand, this existence is a kind of false step or error; if it is the work of an originally blind will, whose most fortunate development is that it comes to itself in order to abolish itself; then the act which perpetuates that existence must appear precisely as it does appear.

With reference to the first fundamental truth of my doctrine, the remark deserves a place here that the shame mentioned above which attaches to the act of generation extends even to the parts which are concerned in this, although, like all other parts, they are given us by nature. This is again a striking proof that not only the actions but even the body of man is to be regarded as the manifestation, the objectification, of his will, and as its work. For he could not be ashamed of a thing which existed without his will.

The act of generation is further related to the world, as the answer is related to the riddle. The world is wide in space and old in time, and of an inexhaustible multiplicity of forms. Yet all this is only the manifestation of the will to live; and the concentration, the focus of this will is the act of generation. Thus in this act the inner nature of the world expresses itself most distinctly. In this regard it is indeed worth noticing that this act itself is also distinctly called "the will" in the very significant German phrase, "*Er verlangte von ihr, sie sollte ihm zu Willen sein*" (He desired her to comply with his wishes). As the most distinct expression of the will, then, this act is the kernel, the compendium, the quintessence of the world. Therefore from it we obtain light as to the nature and tendency of the world: it is the answer to the riddle. Accordingly it is understood under "the tree of knowledge," for after acquaintance with it the eyes of every one are opened as to life, as Byron also says:

"The tree of knowledge has been plucked, — all's known."

— *Don Juan*, i. 128.

It is not less in keeping with this quality that it is the great αρρητον, the open secret, which must never and nowhere be distinctly mentioned, but always and everywhere is understood as the principal matter, and is therefore constantly present to the thoughts of all, wherefore also the slightest allusion to it is instantly understood. The leading part which that act, and what is connected with it, plays in the world, because love intrigues are everywhere, on the one hand, pursued, and, on the other hand, assumed,

is quite in keeping with the importance of this *punctum saliens* of the egg of the world. The source of the amusing is simply the constant concealment of the chief concern.

But see now how the young, innocent, human intellect, when that great secret of the world first becomes known to it, is startled at the enormity! The reason of this is that in the long course which the originally unconscious will had to traverse before it rose to intellect, especially to human, rational intellect, it became so strange to itself that it no longer knows its origin, that *pœnitenda origo*, and now, from the standpoint of pure, and therefore innocent, knowing, is horrified at it.

Since now the focus of the will, *i.e.*, its concentration and highest expression, is the sexual impulse and its satisfaction, this is very significantly and naïvely expressed in the symbolical language of nature through the fact that the individualised will, that is, the man and the brute, makes its entrance into the world through the door of the sexual organs.

The assertion of the will to live, which accordingly has its centre in the act of generation, is in the case of the brute infallible. For the will, which is the *natura naturans*, first arrives at reflection in man. To arrive at reflection means, not merely to know the momentary necessity of the individual will, how to serve it in the pressing present — as is the case with the brute, in proportion to its completeness and its necessities, which go hand in hand — but to have attained a greater breadth of knowledge, by virtue of a distinct remembrance of the past, an approximate anticipation of the future, and thereby a general survey of the individual life, both one's own life and that of others, nay, of existence in general. Really the life of every species of brute, through the thousands of years of its existence, is to a certain extent like a single moment; for it is mere consciousness of the present, without that of the past and the future, and consequently without that of death. In this sense it is to be regarded as a permanent moment, a *Nunc stans*. Here we see, in passing, most distinctly that in general the form of life, or the manifestation of the will with consciousness, is primarily and immediately merely the present. Past and future are added only in the case of man, and indeed merely in conception, are known *in abstracto*, and perhaps illustrated by pictures of the imagination. Thus after the will to live, *i.e.*, the inner being of nature, in the ceaseless striving towards complete objectification and complete enjoyment, has run through the whole series of the brutes, — which often occurs in the various periods of successive

animal series each arising anew on the same planet, — it arrives at last at reflection in the being who is endowed with reason, man. Here now to him the thing begins to be doubtful, the question forces itself upon him whence and wherefore all this is, and chiefly whether the care and misery of his life and effort is really repaid by the gain? "*Le jeu vaut-il bien la chandelle?*" Accordingly here is the point at which, in the light of distinct knowledge, he decides for the assertion or denial of the will to live; although as a rule he can only bring the latter to consciousness in a mythical form. We have consequently no ground for assuming that a still more highly developed objectification of the will is ever reached, anywhere; for it has already reached its turning-point here.

Chapter XLVI.[41] On The Vanity And Suffering Of Life.

Awakened to life out of the night of unconsciousness, the will finds itself an individual, in an endless and boundless world, among innumerable individuals, all striving, suffering, erring; and as if through a troubled dream it hurries back to its old unconsciousness. Yet till then its desires are limitless, its claims inexhaustible, and every satisfied desire gives rise to a new one. No possible satisfaction in the world could suffice to still its longings, set a goal to its infinite cravings, and fill the bottomless abyss of its heart. Then let one consider what as a rule are the satisfactions of any kind that a man obtains. For the most part nothing more than the bare maintenance of this existence itself, extorted day by day with unceasing trouble and constant care in the conflict with want, and with death in prospect. Everything in life shows that earthly happiness is destined to be frustrated or recognised as an illusion. The grounds of this lie deep in the nature of things. Accordingly the life of most men is troubled and short. Those who are comparatively happy are so, for the most part, only apparently, or else, like men of long life, they are the rare exceptions, a possibility of which there had to be, — as decoy-birds. Life presents itself as a continual deception in small things as in great. If it has promised, it does not keep its word, unless to show how little worth desiring were the things desired: thus we are deluded now by hope, now by what was hoped for. If it has given, it did so in order to take. The enchantment of distance shows us paradises which vanish like optical illusions when we have allowed ourselves to be mocked by them. Happiness accordingly always lies in the future, or else in the past, and the present may be compared to a small dark cloud which the wind drives over the sunny plain: before and behind it all is bright, only it itself always casts a shadow. The present is therefore always insufficient; but the future is uncertain, and the past irrevocable. Life with its hourly, daily, weekly, yearly, little, greater, and great misfortunes, with its deluded hopes and its accidents destroying all our calculations, bears so distinctly the impression of something with which we must become disgusted, that it is hard to conceive how one has been able to mistake this and allow oneself to be persuaded that life is there in order to be thankfully enjoyed, and that man exists in order to be happy. Rather that continual illusion and disillusion, and also the nature of life

throughout, presents itself to us as intended and calculated to awaken the conviction that nothing at all is worth our striving, our efforts and struggles, that all good things are vanity, the world in all its ends bankrupt, and life a business which does not cover its expenses; — so that our will may turn away from it.

The way in which this vanity of all objects of the will makes itself known and comprehensible to the intellect which is rooted in the individual, is primarily *time*. It is the form by means of which that vanity of things appears as their perishableness; for on account of this all our pleasures and joys disappear in our hands, and we afterwards ask astonished where they have remained. That nothingness itself is therefore the only *objective* element in time, *i.e.*, that which corresponds to it in the inner nature of things, thus that of which it is the expression. Just on this account time is the *a priori* necessary form of all our perceptions; in it everything must present itself, even we ourselves. Accordingly, first of all, our life is like a payment which one receives in nothing but copper pence, and yet must then give a discharge for: the copper pence are the days; the discharge is death. For at last time makes known the judgment of nature concerning the work of all the beings which appear in it, in that it destroys them: —

“And rightly so, for all that arises
Is worthy only of being destroyed.
Hence were it better that nothing arose.”

Thus old age and death, to which every life necessarily hurries on, are the sentence of condemnation on the will to live, coming from the hands of nature itself, and which declares that this will is an effort which frustrates itself. “What thou hast wished,” it says, “ends thus: desire something better.” Hence the instruction which his life affords to every one consists, as a whole, in this, that the objects of his desires continually delude, waver, and fall, and accordingly bring more misery than joy, till at last the whole foundation upon which they all stand gives way, in that his life itself is destroyed and so he receives the last proof that all his striving and wishing was a perversity, a false path: —

“Then old age and experience, hand in hand,
Lead him to death, and make him understand,
After a search so painful and so long,
That all his life he has been in the wrong.”

We shall, however, enter into the details of the matter, for it is in these views that I have met with most contradiction. First of all, I have to confirm by the following remarks the proof given in the text of the negative nature of all satisfaction, thus of all pleasure and all happiness, in opposition to the positive nature of pain.

We feel pain, but not painlessness; we feel care, but not the absence of care; fear, but not security. We feel the wish as we feel hunger and thirst; but as soon as it has been fulfilled, it is like the mouthful that has been taken, which ceases to exist for our feeling the moment it is swallowed. Pleasures and joys we miss painfully whenever they are wanting; but pains, even when they cease after having long been present, are not directly missed, but at the most are intentionally thought of by means of reflection. For only pain and want can be felt positively, and therefore announce themselves; well-being, on the other hand, is merely negative. Therefore we do not become conscious of the three greatest blessings of life, health, youth, and freedom, so long as we possess them, but only after we have lost them; for they also are negations. We only observe that days of our life were happy after they have given place to unhappy ones. In proportion as pleasures increase, the susceptibility for them decreases: what is customary is no longer felt as a pleasure. Just in this way, however, is the susceptibility for suffering increased, for the loss of what we are accustomed to is painfully felt. Thus the measure of what is necessary increases through possession, and thereby the capacity for feeling pain. The hours pass the quicker the more agreeably they are spent, and the slower the more painfully they are spent; because pain, not pleasure, is the positive, the presence of which makes itself felt. In the same way we become conscious of time when we are bored, not when we are diverted. Both these cases prove that our existence is most happy when we perceive it least, from which it follows that it would be better not to have it. Great and lively joy can only be conceived as the consequence of great misery, which has preceded it; for nothing can be added to a state of permanent satisfaction but some amusement, or the satisfaction of vanity. Hence all poets are obliged to bring their heroes into anxious and painful situations, so that they may be able to free them from them. Dramas and Epics accordingly always describe only fighting, suffering, tormented men; and every romance is a rareeshow in which we observe the spasms and convulsions of the agonised human heart. Walter Scott has naïvely expressed this æsthetic necessity in

the conclusion to his novel, "Old Mortality." Voltaire, who was so highly favoured both by nature and fortune, says, in entire agreement with the truth proved by me: "*Le bonheur n'est qu'un rève, et la douleur est réelle*." And he adds: "*Il y a quatre-vingts ans que je l'éprouve. Je n'y sais autre chose que me résigner, et me dire que les mouches sont nées pour être mangées par les araignées, et les hommes pour être dévorés par les chagrins*."

Before so confidently affirming that life is a blessing worth desiring or giving thanks for, let one compare calmly the sum of the possible pleasures which a man can enjoy in his life with the sum of the possible sorrows which may come to him in his life. I believe the balance will not be hard to strike. At bottom, however, it is quite superfluous to dispute whether there is more good or evil in the world: for the mere existence of evil decides the matter. For the evil can never be annulled, and consequently can never be balanced by the good which may exist along with it or after it.

"*Mille piacer' non vagliono un tormento.*" — Petr.

(A thousand pleasures are not worth one torment.)

For that a thousand had lived in happiness and pleasure would never do away with the anguish and death-agony of a single one; and just as little does my present well-being undo my past suffering. If, therefore, the evils in the world were a hundred times less than is the case, yet their mere existence would be sufficient to establish a truth which may be expressed in different ways, though always somewhat indirectly, the truth that we have not to rejoice but rather to mourn at the existence of the world; — that its non-existence would be preferable to its existence; — that it is something which at bottom ought not to be, &c., &c. Very beautiful is Byron's expression of this truth: —

"*Our life is a false nature*,— 'tis not in
The harmony of things, this hard decree,
This uneradicable taint of sin,
This boundless Upas, this all-blasting tree
Whose root is earth, whose leaves and branches be
The skies, which rain their plagues on men like dew —
Disease, death, bondage — all the woes we see —
And worse, the woes we see not — which throb through
The immedicable soul, with heart-aches ever new."

If the world and life were an end in themselves, and accordingly required theoretically no justification and practically no indemnification or

compensation, but existed, for instance, as Spinoza and the Spinozists of the present day represent it, as the single manifestation of a God, who, *animi causa*, or else in order to mirror himself, undertook such an evolution of himself; and hence its existence neither required to be justified by reasons nor redeemed by results; — then the sufferings and miseries of life would not indeed have to be fully equalled by the pleasures and well-being in it; for this, as has been said, is impossible, because my present pain is never abolished by future joys, for the latter fill their time as the former fills its time: but there would have to be absolutely no suffering, and death also would either have not to be, or else to have no terrors for us. Only thus would life pay for itself.

But since now our state is rather something which had better not be, everything about us bears the trace of this, — just as in hell everything smells of sulphur — for everything is always imperfect and illusory, everything agreeable is displaced by something disagreeable, every enjoyment is only a half one, every pleasure introduces its own disturbance, every relief new difficulties, every aid of our daily and hourly need leaves us each moment in the lurch and denies its service, the step upon which we place our foot so often gives way under us, nay, misfortunes great and small are the element of our life; and, in a word, we are like Phineus, whose food was all tainted and made uneatable by the harpies.[42] Two remedies for this are tried: first, ευλαβεια, *i.e.*, prudence, foresight, cunning; it does not fully instruct us, is insufficient, and leads to defeat. Secondly, the stoical equanimity which seeks to arm us against all misfortunes by preparedness for everything and contempt of all: practically it becomes cynical renunciation, which prefers once for all to reject all means of relief and all alleviations — it reduces us to the position of dogs, like Diogenes in his tub. The truth is, we ought to be wretched, and we are so. The chief source of the serious evils which affect men is man himself: *homo homini lupus*. Whoever keeps this last fact clearly in view beholds the world as a hell, which surpasses that of Dante in this respect, that one man must be the devil of another. For this, one is certainly more fitted than another; an arch-fiend, indeed, more fitted than all others, appearing in the form of a conqueror, who places several hundred thousand men opposite each other, and says to them: “To suffer and die is your destiny; now shoot each other with guns and cannons,” and they do so.

In general, however, the conduct of men towards each other is characterised as a rule by injustice, extreme unfairness, hardness, nay, cruelty: an opposite course of conduct appears only as an exception. Upon this depends the necessity of the State and legislation, and upon none of your false pretences. But in all cases which do not lie within the reach of the law, that regardlessness of his like, peculiar to man, shows itself at once; a regardlessness which springs from his boundless egoism, and sometimes also from wickedness. How man deals with man is shown, for example, by negro slavery, the final end of which is sugar and coffee. But we do not need to go so far: at the age of five years to enter a cotton-spinning or other factory, and from that time forth to sit there daily, first ten, then twelve, and ultimately fourteen hours, performing the same mechanical labour, is to purchase dearly the satisfaction of drawing breath. But this is the fate of millions, and that of millions more is analogous to it.

We others, however, can be made perfectly miserable by trifling misfortunes; perfectly happy, not by the world. Whatever one may say, the happiest moment of the happy man is the moment of his falling asleep, and the unhappiest moment of the unhappy that of his awaking. An indirect but certain proof of the fact that men feel themselves unhappy, and consequently are so, is also abundantly afforded by the fearful envy which dwells in us all, and which in all relations of life, on the occasion of any superiority, of whatever kind it may be, is excited, and cannot contain its poison. Because they feel themselves unhappy, men cannot endure the sight of one whom they imagine happy; he who for the moment feels himself happy would like to make all around him happy also, and says:

"*Que tout le monde ici soit heureux de ma joie.*"

If life were in itself a blessing to be prized, and decidedly to be preferred to non-existence, the exit from it would not need to be guarded by such fearful sentinels as death and its terrors. But who would continue in life as it is if death were less terrible? And again, who could even endure the thought of death if life were a pleasure! But thus the former has still always this good, that it is the end of life, and we console ourselves with regard to the suffering of life with death, and with regard to death with the suffering of life. The truth is, that the two inseparably belong to each other, for together they constitute a deviation from the right path, to return to which is as difficult as it is desirable.

If the world were not something which, expressed *practically*, ought not to be, it would also not be *theoretically* a problem; but its existence would either require no explanation, inasmuch as it would be so entirely self-evident that wonder concerning it or a question about it could arise in no mind, or its end would present itself unmistakably. Instead of this, however, it is indeed an insoluble problem; for even the most perfect philosophy will yet always contain an unexplained element, like an insoluble deposit or the remainder which the irrational relation of two quantities always leaves over. Therefore if one ventures to raise the question why there is not rather nothing than this world, the world cannot be justified from itself, no ground, no final cause of its existence can be found in itself, it cannot be shown that it exists for its own sake, *i.e.*, for its own advantage. In accordance with my teaching, this can certainly be explained from the fact that the principle of its existence is expressly one which is without ground, a blind will to live, which as thing in itself cannot be made subject to the principle of sufficient reason, which is merely the form of the phenomenon, and through which alone every why is justified. But this also agrees with the nature of the world, for only a blind will, no seeing will, could place itself in the position in which we behold ourselves. A seeing will would rather have soon made the calculation that the business did not cover the cost, for such a mighty effort and struggle with the straining of all the powers, under constant care, anxiety, and want, and with the inevitable destruction of every individual life, finds no compensation in the ephemeral existence itself, which is so obtained, and which passes into nothing in our hands. Hence, then, the explanation of the world from the Anaxagorean νους, *i.e.*, from a will accompanied by *knowledge*, necessarily demands optimism to excuse it, which accordingly is set up and maintained in spite of the loudly crying evidence of a whole world full of misery. Life is there given out to be a gift, while it is evident that every one would have declined such a gift if he could have seen it and tested it beforehand; just as Lessing admired the understanding of his son, who, because he had absolutely declined to enter life, had to be forcibly brought into it with the forceps, but was scarcely there when he hurried away from it again. On the other hand, it is then well said that life should be, from one end to the other, only a lesson; to which, however, any one might reply: "For this very reason I wish I had been left in the peace of the all-sufficient nothing, where I would have had no need of lessons or of anything else." If indeed it should now be added that he must

one day give an account of every hour of his life, he would be more justified in himself demanding an account of why he had been transferred from that rest into such a questionable, dark, anxious, and painful situation. To this, then, we are led by false views. For human existence, far from bearing the character of a *gift*, has entirely the character of a *debt* that has been contracted. The calling in of this debt appears in the form of the pressing wants, tormenting desires, and endless misery established through this existence. As a rule, the whole lifetime is devoted to the paying off of this debt; but this only meets the interest. The payment of the capital takes place through death. And when was this debt contracted? At the begetting.

Accordingly, if we regard man as a being whose existence is a punishment and an expiation, we then view him in a right light. The myth of the fall (although probably, like the whole of Judaism, borrowed from the Zend-Avesta: Bundahish, 15), is the only point in the Old Testament to which I can ascribe metaphysical, although only allegorical, truth; indeed it is this alone that reconciles me to the Old Testament. Our existence resembles nothing so much as the consequence of a false step and a guilty desire. New Testament Christianity, the ethical spirit of which is that of Brahmanism and Buddhism, and is therefore very foreign to the otherwise optimistic spirit of the Old Testament, has also, very wisely, linked itself on precisely to that myth: indeed, without this it would have found no point of connection with Judaism at all. If any one desires to measure the degree of guilt with which our existence is tainted, then let him look at the suffering that is connected with it. Every great pain, whether bodily or mental, declares what we deserve: for it could not come to us if we did not deserve it. That Christianity also regards our existence in this light is shown by a passage in Luther's Commentary on Galatians, chap. 3, which I only have beside me in Latin: "*Sumus autem nos omnes corporibus et rebus subjecti Diabolo, et hospites sumus in mundo, cujus ipse princeps et Deus est. Ideo panis, quem edimus, potus, quem bibimus, vestes, quibus utimur, imo aër et totum quo vivimus in carne, sub ipsius imperio est.*" An outcry has been made about the melancholy and disconsolate nature of my philosophy; yet it lies merely in the fact that instead of inventing a future hell as the equivalent of sin, I show that where guilt lies in the world there is also already something akin to hell; but whoever is inclined to deny this can easily experience it.

And to this world, to this scene of tormented and agonised beings, who only continue to exist by devouring each other, in which, therefore, every ravenous beast is the living grave of thousands of others, and its self-maintenance is a chain of painful deaths; and in which the capacity for feeling pain increases with knowledge, and therefore reaches its highest degree in man, a degree which is the higher the more intelligent the man is; to this world it has been sought to apply the system of optimism, and demonstrate to us that it is the best of all possible worlds. The absurdity is glaring. But an optimist bids me open my eyes and look at the world, how beautiful it is in the sunshine, with its mountains and valleys, streams, plants, animals, &c. &c. Is the world, then, a rareeshow? These things are certainly beautiful to *look at*, but to *be* them is something quite different. Then comes a teleologist, and praises to me the wise arrangement by virtue of which it is taken care that the planets do not run their heads together, that land and sea do not get mixed into a pulp, but are held so beautifully apart, also that everything is neither rigid with continual frost nor roasted with heat; in the same way, that in consequence of the obliquity of the ecliptic there is no eternal spring, in which nothing could attain to ripeness, &c. &c. But this and all like it are mere *conditiones sine quibus non*. If in general there is to be a world at all, if its planets are to exist at least as long as the light of a distant fixed star requires to reach them, and are not, like Lessing's son, to depart again immediately after birth, then certainly it must not be so clumsily constructed that its very framework threatens to fall to pieces. But if one goes on to the results of this applauded work, considers the players who act upon the stage which is so durably constructed, and now sees how with sensibility pain appears, and increases in proportion as the sensibility develops to intelligence, and then how, keeping pace with this, desire and suffering come out ever more strongly, and increase till at last human life affords no other material than this for tragedies and comedies, then whoever is honest will scarcely be disposed to set up hallelujahs. David Hume, in his "Natural History of Religion," §§ 6, 7, 8, and 13, has also exposed, mercilessly but with convincing truth, the real though concealed source of these last. He also explains clearly in the tenth and eleventh books of his "Dialogues on Natural Religion," with very pertinent arguments, which are yet of quite a different kind from mine, the miserable nature of this world and the untenableness of all optimism; in doing which he attacks this in its origin. Both works of Hume's are as well

worth reading as they are unknown at the present day in Germany, where, on the other hand, incredible pleasure is found, patriotically, in the most disgusting nonsense of home-bred boastful mediocrities, who are proclaimed great men. Hamann, however, translated these dialogues; Kant went through the translation, and late in life wished to induce Hamann's son to publish them because the translation of Platner did not satisfy him (see Kant's biography by F. W. Schubert, pp. 81 and 165). From every page of David Hume there is more to be learned than from the collected philosophical works of Hegel, Herbart, and Schleiermacher together.

The founder of systematic optimism, again, is Leibnitz whose philosophical merit I have no intention of denying although I have never succeeded in thinking myself into the monadology, pre-established harmony, and *identitas indiscernibilium*. His "*Nouveaux essays sur l'entendement*" are, however, merely an excerpt, with a full yet weak criticism, with a view to correction, of Locke's work which is justly of world-wide reputation. He here opposes Locke with just as little success as he opposes Newton in the "*Tentamen de motuum cœlestium causis*," directed against the system of gravitation. The "Critique of Pure Reason" is specially directed against this Leibnitz-Wolfian philosophy, and has a polemical, nay, a destructive relation to it, just as it is related to Locke and Hume as a continuation and further construction. That at the present day the professors of philosophy are on all sides engaged in setting Leibnitz, with his juggling, upon his legs again, nay, in glorifying him, and, on the other hand, in depreciating and setting aside Kant as much as possible, has its sufficient reason in the *primum vivere*; the "Critique of Pure Reason" does not admit of one giving out Judaistic mythology as philosophy, nor of one speaking, without ceremony, of the "soul" as a given reality, a well-known and well-accredited person, without giving account of how one arrived at this conception, and what justification one has for using it scientifically. But *primum vivere, deinde philosophari*! Down with Kant, *vivat* our Leibnitz! To return, then, to Leibnitz, I cannot ascribe to the Théodicée, as a methodical and broad unfolding of optimism, any other merit than this, that it gave occasion later for the immortal "*Candide*" of the great Voltaire; whereby certainly Leibnitz's often-repeated and lame excuse for the evil of the world, that the bad sometimes brings about the good, received a confirmation which was unexpected by him. Even by the name of his hero Voltaire indicates that it only requires sincerity to recognise the opposite of

optimism. Really upon this scene of sin, suffering, and death optimism makes such an extraordinary figure that one would be forced to regard it as irony if one had not a sufficient explanation of its origin in the secret source of it (insincere flattery, with insulting confidence in its success), which, as was mentioned above, is so delightfully disclosed by Hume.

But indeed to the palpably sophistical proofs of Leibnitz that this is the best of all possible worlds, we may seriously and honestly oppose the proof that it is the worst of all possible worlds. For possible means, not what one may construct in imagination, but what can actually exist and continue. Now this world is so arranged as to be able to maintain itself with great difficulty; but if it were a little worse, it could no longer maintain itself. Consequently a worse world, since it could not continue to exist, is absolutely impossible: thus this world itself is the worst of all possible worlds. For not only if the planets were to run their heads together, but even if any one of the actually appearing perturbations of their course, instead of being gradually balanced by others, continued to increase, the world would soon reach its end. Astronomers know upon what accidental circumstances — principally the irrational relation to each other of the periods of revolution — this depends, and have carefully calculated that it will always go on well; consequently the world also can continue and go on. We will hope that, although Newton was of an opposite opinion, they have not miscalculated, and consequently that the mechanical perpetual motion realised in such a planetary system will not also, like the rest, ultimately come to a standstill. Again, under the firm crust of the planet dwell the powerful forces of nature which, as soon as some accident affords them free play, must necessarily destroy that crust, with everything living upon it, as has already taken place at least three times upon our planet, and will probably take place oftener still. The earthquake of Lisbon, the earthquake of Haiti, the destruction of Pompeii, are only small, playful hints of what is possible. A small alteration of the atmosphere, which cannot even be chemically proved, causes cholera, yellow fever, black death, &c., which carry off millions of men; a somewhat greater alteration would extinguish all life. A very moderate increase of heat would dry up all the rivers and springs. The brutes have received just barely so much in the way of organs and powers as enables them to procure with the greatest exertion sustenance for their own lives and food for their offspring; therefore if a brute loses a limb, or even the full use of one, it must generally perish. Even of the

human race, powerful as are the weapons it possesses in understanding and reason, nine-tenths live in constant conflict with want, always balancing themselves with difficulty and effort upon the brink of destruction. Thus throughout, as for the continuance of the whole, so also for that of each individual being the conditions are barely and scantily given, but nothing over. The individual life is a ceaseless battle for existence itself; while at every step destruction threatens it. Just because this threat is so often fulfilled provision had to be made, by means of the enormous excess of the germs, that the destruction of the individuals should not involve that of the species, for which alone nature really cares. The world is therefore as bad as it possibly can be if it is to continue to be at all. *Q. E. D.* The fossils of the entirely different kinds of animal species which formerly inhabited the planet afford us, as a proof of our calculation, the records of worlds the continuance of which was no longer possible, and which consequently were somewhat worse than the worst of possible worlds.

Optimism is at bottom the unmerited self-praise of the real originator of the world, the will to live, which views itself complacently in its works; and accordingly it is not only a false, but also a pernicious doctrine. For it presents life to us as a desirable condition, and the happiness of man as the end of it. Starting from this, every one then believes that he has the most just claim to happiness and pleasure; and if, as is wont to happen, these do not fall to his lot, then he believes that he is wronged, nay, that he loses the end of his existence; while it is far more correct to regard work, privation, misery, and suffering, crowned by death, as the end of our life (as Brahmanism and Buddhism, and also genuine Christianity do); for it is these which lead to the denial of the will to live. In the New Testament the world is represented as a valley of tears, life as a process of purifying or refining, and the symbol of Christianity is an instrument of torture. Therefore, when Leibnitz, Shaftesbury, Bolingbroke, and Pope brought forward optimism, the general offence which it gave depended principally upon the fact that optimism is irreconcilable with Christianity; as Voltaire states and explains in the preface to his excellent poem, "*Le désastre de Lisbonne*," which is also expressly directed against optimism. This great man, whom I so gladly praise, in opposition to the abuse of venal German ink-slingers, is placed decidedly higher than Rousseau by the insight to which he attained in three respects, and which prove the greater depth of his thinking: (1) the recognition of the preponderating magnitude of the evil

and misery of existence with which he is deeply penetrated; (2) that of the strict necessity of the acts of will; (3) that of the truth of Locke's principle, that what thinks may also be material: while Rousseau opposes all this with declamations in his "*Profession de foi du vicaire Savoyard*," a superficial Protestant pastor's philosophy; as he also in the same spirit attacks the beautiful poem of Voltaire which has just been referred to with ill-founded, shallow, and logically false reasoning, in the interests of optimism, in his long letter to Voltaire of 18th August 1756, which is devoted simply to this purpose. Indeed, the fundamental characteristic and the πρωτον ψευδος of Rousseau's whole philosophy is this, that in the place of the Christian doctrine of original sin, and the original depravity of the human race, he puts an original goodness and unlimited perfectibility of it, which has only been led astray by civilisation and its consequences, and then founds upon this his optimism and humanism.

As in "*Candide*" Voltaire wages war in his facetious manner against optimism, Byron has also done so in his serious and tragic style, in his immortal masterpiece, "Cain," on account of which he also has been honoured with the invectives of the obscurantist, Friedrich Schlegel. If now, in conclusion, to confirm my view, I were to give what has been said by great men of all ages in this anti-optimistic spirit, there would be no end to the quotations, for almost every one of them has expressed in strong language his knowledge of the misery of this world. Thus, not to confirm, but merely to embellish this chapter, a few quotations of this kind may be given at the end of it.

First of all, let me mention here that the Greeks, far as they were from the Christian and lofty Asiatic conception of the world, and although they decidedly stood at the point of view of the assertion of the will, were yet deeply affected by the wretchedness of existence. This is shown even by the invention of tragedy, which belongs to them. Another proof of it is afforded us by the custom of the Thracians, which is first mentioned by Herodotus, though often referred to afterwards — the custom of welcoming the new-born child with lamentations, and recounting all the evils which now lie before it; and, on the other hand, burying the dead with mirth and jesting, because they are no longer exposed to so many and great sufferings. In a beautiful poem preserved for us by Plutarch (*De audiend. poët. in fine*) this runs thus: —

"Τον φυντα θρηνειν, εις ὁσ᾽ ερχεται κακα

Τον δ᾽αυ θανοντα και πονων πεπαυμενον
Χαιροντας ευφημουντας εκπεμπειν δομων.”
(*Lugere genitum, tanta qui intrarit mala:*
At morte si quis finiisset miserias,
Hunc laude amicos atque lætitia exsequi.)

It is not to be attributed to historical relationship, but to the moral identity of the matter, that the Mexicans welcomed the new-born child with the words, “My child, thou art born to endure; therefore endure, suffer, and keep silence.” And, following the same feeling, Swift (as Walter Scott relates in his Life of Swift) early adopted the custom of keeping his birthday not as a time of joy but of sadness, and of reading on that day the passage of the Bible in which Job laments and curses the day on which it was said in the house of his father a man-child is born.

Well known and too long for quotation is the passage in the “Apology of Socrates,” in which Plato makes this wisest of mortals say that death, even if it deprives us of consciousness for ever, would be a wonderful gain, for a deep, dreamless sleep every day is to be preferred even to the happiest life.

A saying of Heraclitus runs: “Τῳ ουν βιῳ ονομα μεν βιος, εργον δε θανατος.” (*Vitæ nomen quidem est vita, opus autem mors. Etymologicum magnum, voce* Βιος; also *Eustath. ad Iliad.*, i. p. 31.)

The beautiful lines of the “Theogony” are famous: —

“Αρχην μεν μη φυναι επιχθονιοισιν αριστον,
Μηδ᾽ εισιδειν αυγας οξεος ἡελιου;
Φυντα δ᾽ ὁπως ωκιστα πυλας Αϊδαο περησαι,
Και κεισθαι πολλην γην επαμησαμενον.”
(*Optima sors homini natum non esse, nec unquam.*
Adspexisse diem, flammiferumque jubar.
Altera jam genitum demitti protinus Orco,
Et pressum multa mergere corpus humo.)

Sophocles, in “Œdipus Colonus” (1225), has the following abbreviation of the same: —

“Μη φυναι τον ἁπαντα νικα
λογον; το δ᾽ επει φανῃ,
βηναι κειθεν, ὁθεν περ ἡκει,
πολυ δευτερον, ὡς ταχιστα.”

(*Natum non esse sortes vincit alias omnes: proxima autem est, ubi quis in lucem editus fuerit, eodem redire, unde venit, quam ocissime.*)

Euripides says: —

“Πας δ᾽οδυνηρος βιος ανθρωπων,
Κ᾽ουκ εστι πονων αναπαυσις.”

(*Omnis hominum vita est plena dolore,*
Nec datur laborum remissio.)

— Hippol, 189.

And Homer already said: —

“Ου μεν γαρ τι εστιν οϊζυρωτερον ανδρος
Παντων, ὁσσα δε γαιαν επι πνεει τε και ἑρπει.”

(*Non enim quidquam alicubi est calamitosius homine*
Omnium, quotquot super terram spirantque et moventur.)

— Il. xvii. 446.

Even Pliny says: “*Quapropter hoc primum quisque in remediis animi sui habeat, ex omnibus bonis, quæ homini natura tribuit, nullum melius esse tempestiva morte*” (*Hist. Nat.* 28, 2).

Shakspeare puts the words in the mouth of the old king Henry IV.: —

“O heaven! that one might read the book of fate,
And see the revolution of the times,
... how chances mock,
And changes fill the cup of alteration
With divers liquors! O, if this were seen,
The happiest youth, — viewing his progress through,
What perils past, what crosses to ensue, —
Would shut the book, and sit him down and die.”

Finally, Byron: —

“Count o’er the joys thine hours have seen,
Count o’er thy days from anguish free,
And know, whatever thou hast been,
’Tis something better not to be.”

Baltazar Gracian also brings the misery of our existence before our eyes in the darkest colours in the “Criticon,” Parte i., Crisi 5, just at the beginning, and Crisi 7 at the end, where he explicitly represents life as a tragic farce.

Yet no one has so thoroughly and exhaustively handled this subject as, in our own day, Leopardi. He is entirely filled and penetrated by it: his theme is everywhere the mockery and wretchedness of this existence; he presents it upon every page of his works, yet in such a multiplicity of forms and applications, with such wealth of imagery that he never wearies us, but, on the contrary, is throughout entertaining and exciting.

Chapter XLVII.[43] On Ethics.

Here is the great gap which occurs in these supplements, on account of the circumstance that I have already dealt with moral philosophy in the narrower sense in the two prize essays published under the title, "*Die Grundprobleme der Ethik*," an acquaintance with which is assumed, as I have said, in order to avoid useless repetition. Therefore there only remains for me here a small gleaning of isolated reflections which could not be discussed in that work, the contents of which were, in the main, prescribed by the Academies; least of all those reflections which demand a higher point of view than that which is common to all, and which I was there obliged to adhere to. Accordingly it will not surprise the reader to find these reflections here in a very fragmentary collection. This collection again has been continued in the eighth and ninth chapters of the second volume of the Parerga.

That moral investigations are incomparably more difficult than physical, and in general than any others, results from the fact that they are almost immediately concerned with the thing in itself, namely, with that manifestation of it in which, directly discovered by the light of knowledge, it reveals its nature as *will*. Physical truths, on the other hand, remain entirely in the province of the idea, *i.e.*, of the phenomenon, and merely show how the lowest manifestations of the will present themselves in the idea in conformity to law. Further, the consideration of the world from the *physical* side, however far and successfully it may be pursued, is in its results without any consolation for us: on the *moral* side alone is consolation to be found; for here the depths of our own inner nature disclose themselves to the consideration.

But my philosophy is the only one which confers upon ethics its complete and whole rights; for only if the true nature of man is his own *will*, and consequently he is, in the strictest sense, his own work, are his deeds really entirely his and to be ascribed to him. On the other hand, whenever he has another origin, or is the work of a being different from himself, all his guilt falls back upon this origin, or originator. For *operari sequitur esse*.

To connect the force which produces the phenomenon of the world, and consequently determines its nature, with the morality of the disposition or character, and thus to establish a *moral* order of the world as the foundation

of the *physical*, — this has been since Socrates the problem of philosophy. Theism solved it in a childish manner, which could not satisfy mature humanity. Therefore pantheism opposed itself to it whenever it ventured to do so, and showed that nature bears in itself the power by virtue of which it appears. With this, however, ethics had necessarily to be given up. Spinoza, indeed, attempts here and there to preserve it by means of sophistry, but for the most part gives it up altogether, and, with a boldness which excites astonishment and repugnance, explains the distinction between right and wrong, and in general between good and evil, as merely conventional, thus in itself empty (for example, *Eth.* iv., prop. 37, schol. 2). After having met with unmerited neglect for more than a hundred years, Spinoza has, in general, become too much esteemed in this century through the reaction caused by the swing of the pendulum of opinion. All pantheism must ultimately be overthrown by the inevitable demands of ethics, and then by the evil and suffering of the world. If the world is a theophany, then all that man, or even the brute, does is equally divine and excellent; nothing can be censurable, and nothing more praiseworthy than the rest: thus there is no ethics. Hence, in consequence of the revived Spinozism of our own day, thus of pantheism, the treatment of ethics has sunk so low and become so shallow that it has been made a mere instruction as to the proper life of a citizen and a member of a family, in which the ultimate end of human existence is supposed to consist: thus in methodical, complete, smug, and comfortable philistinism. Pantheism, indeed, has only led to such shallow vulgarisms through the fact that (by a shameful misuse of the *e quovis ligno fit Mercurius*) a common mind, Hegel, has, by the well-known means, been falsely stamped as a great philosopher, and a herd of his disciples, at first suborned, afterwards only stupid, received his weighty words. Such outrages on the human mind do not remain unpunished: the seed has sprouted. In the same spirit it was then asserted that ethics should have for its material not the conduct of individuals, but that of nations, that this alone was a theme worthy of it. Nothing can be more perverse than this view, which rests on the most vulgar realism. For in every individual appears the whole undivided will to live, the thing in itself, and the microcosm is like the macrocosm. The masses have no more content than each individual. Ethics is concerned not with actions and their results, but with willing, and willing itself takes place only in the individual. Not the fate of nations, which exists only in the phenomenon, but that of the individual is decided

morally. Nations are really mere abstractions; individuals alone actually exist. Thus, then, is pantheism related to ethics. But the evil and misery of the world are not in accord even with theism; hence it sought assistance from all kinds of evasions, theodicies, which yet were irretrievably overthrown by the arguments of Hume and Voltaire. Pantheism, however, is completely untenable in the presence of that bad side of the world. Only when the world is regarded entirely from without and from the *physical* side alone, and nothing else is kept in view but the constant restorative order, and the comparative imperishableness of the whole which is thereby introduced, is it perhaps possible to explain it as a god, yet always only symbolically. But if one enters within, thus considers also the *subjective* and *moral* side, with its preponderance of want, suffering, and misery, of dissension, wickedness, madness, and perversity, then one soon becomes conscious with horror that the last thing imaginable one has before one is a theophany. I, however, have shown, and especially in my work "*Ueber den Willen in der Natur*" have proved, that the force which works and acts in nature is identical with the will in us. Thereby the moral order of the world is brought into direct connection with the force which produces the phenomenon of the world. For the phenomenon of the will must exactly correspond to its nature. Upon this depends the exposition of eternal justice given in §§ 63 and 64 of the first volume, and the world, although subsisting by its own power, receives throughout a *moral* tendency. Accordingly the problem which has been discussed from the time of Socrates is now for the first time really solved, and the demand of thinking reason directed to morality is satisfied. Yet I have never professed to propound a philosophy which leaves no questions unanswered. In this sense philosophy is really impossible: it would be the science of omniscience. But *est quadam prodire tenus, si non datur ultra*: there is a limit to which reflection can penetrate and can so far lighten the night of our existence, although the horizon always remains dark. My doctrine reaches this limit in the will to live, which in its own manifestation asserts or denies itself. To wish, however, to go beyond this is, in my eyes, like wishing to fly beyond the atmosphere. We must stop there; even although new problems arise out of those which have been solved. Besides this, however, we must refer to the fact that the validity of the principle of sufficient reason is limited to the phenomenon; this was the theme of my first essay on that principle, which was published as early as 1813.

I now go on to supplement particular points, and shall begin by supporting, with two passages from classical poetry, my explanation of weeping given in § 67 of the first volume, that it springs from sympathy the object of which is one's own self. At the end of the eighth book of the "Odyssey," Ulysses, who in all his many sorrows is never represented as weeping, bursts into tears, when, still unknown, he hears his early heroic life and deeds sung by the bard Demodocus in the palace of the Phæacian king, for this remembrance of the brilliant period of his life contrasts with his present wretchedness. Thus not this itself directly, but the objective consideration of it, the picture of his present summoned up by his past, calls forth his tears; he feels sympathy with himself. Euripides makes the innocently condemned Hypolytus, bemoaning his own fate, express the same feeling:

"Φευ ειθ᾽ ην εμαυτον προσβλεπειν εναντιον

στανθ᾽, ὡς εδακρυς᾽, ὁια πασχομεν κακα" (1084).

(*Heu, si liceret mihi, me ipsum extrinsecus spectare, quantopere deflerem mala, quæ patior.*)

Finally, as a proof of my explanation, an anecdote may be given here which I take from the English journal *The Herald* of the 16th July 1836. A client, when he had heard his case set forth by his counsel in court, burst into a flood of tears, and cried, "I never knew I had suffered half so much till I heard it here to-day."

I have shown in § 55 of the first volume how, notwithstanding the unalterable nature of the character, *i.e.*, of the special fundamental will of a man, a real moral repentance is yet possible. I wish, however, to add the following explanation, which I must preface by a few definitions. *Inclination* is every strong susceptibility of the will for motives of a certain kind. *Passion* is an inclination so strong that the motives which excite it exercise a power over the will, which is stronger than that of every possible motive that can oppose them; thus its mastery over the will becomes absolute, and consequently with reference to it the will is *passive* or *suffering*. It must, however, be remarked here that passions seldom reach the degree at which they fully answer to the definition, but rather bear their name as mere approximations to it: therefore there are then still counter-motives which are able at least to restrict their effect, if only they appear distinctly in consciousness. The *emotion* is just as irresistible, but yet only a passing excitement of the will, by a motive which receives its power, not

from a deeply rooted inclination, but merely from the fact that, appearing suddenly, it excludes for the moment the counter-effect of all other motives, for it consists of an idea, which completely obscures all others by its excessive vividness, or, as it were, conceals them entirely by its too close proximity, so that they cannot enter consciousness and act on the will, whereby, therefore, the capacity for reflection, and with it *intellectual freedom*, is to a certain extent abolished. Accordingly the emotion is related to the passion as delirium to madness.

Moral repentance is now conditioned by the fact that before the act the inclination to it did not leave the intellect free scope, because it did not allow it to contemplate clearly and fully the counter-motives, but rather turned it ever anew to the motives in its own favour. But now, after the act has been performed, these motives are, by this itself, neutralised, and consequently have become ineffective. Now reality brings before the intellect the counter-motives as the consequences of the act which have already appeared; and the intellect now knows that they would have been the stronger if it had only adequately contemplated and weighed them. Thus the man becomes conscious that he has done what was really not in accordance with his will. This knowledge is repentance, for he has not acted with full intellectual freedom; for all the motives did not attain to efficiency. What excluded the motives opposed to the action was in the case of the hasty action the emotion, and in the case of the deliberate action the passion. It has also often depended upon the circumstance that his reason certainly presented to him the counter-motives in the abstract, but was not supported by a sufficiently strong imagination to present to him their whole content and true significance in images. Examples of what has been said are the cases in which revenge, jealousy, or avarice have led to murder. After it is committed they are extinguished, and now justice, sympathy, the remembrance of former friendship, raise their voices and say all that they would have said before if they had been allowed to speak. Then enters the bitter repentance, which says, “If it were not done it would never happen.” An incomparable representation of this is afforded by the old Scottish ballad, which has also been translated by Herder, “Edward, Edward.” In an analogous manner, the neglect of one’s own good may occasion an egotistical repentance. For example, when an otherwise unadvisable marriage is concluded in consequence of passionate love, which now is extinguished just by the marriage, and for the first time the counter-motives

of personal interest, lost independence, &c., &c., come into consciousness, and speak as they would have spoken before if they had been allowed utterance. All such actions accordingly spring from a relative weakness of intellect, because it lets itself be mastered by the will, just where its function as the presenter of motives ought to have been inexorably fulfilled, without allowing itself to be disturbed by the will. The vehemence of the will is here only *indirectly* the cause, in that it interferes with the intellect, and thereby prepares for itself repentance. The *reasonableness* of the character σωφροσυνη, which is opposed to passionateness, really consists in this, that the will never overpowers the intellect to such an extent as to prevent it from correctly exercising its function of the distinct, full, and clear exposition of the motives in the abstract for the reason, in the concrete for the imagination. Now this may just as well depend upon the moderation and mildness of the will as upon the strength of the intellect. All that is required is that the latter should be *relatively* strong enough for the will that is present, thus that the two should stand in a suitable relation to each other.

The following explanations have still to be added to the fundamental characteristics of the philosophy of law expounded in § 62 of the first volume, and also in my prize essay on the foundation of morals, § 17.

Those who, with Spinoza, deny that there is a right apart from the State, confound the means for enforcing the right with the right itself. Certainly the right is insured protection only in the State. But it itself exists independently of the State. For by force it can only be suppressed, never abolished. Accordingly the State is nothing more than an institution for protection, which has become necessary through the manifold attacks to which man is exposed, and which he would not be able to ward off alone, but only in union with others. So, then, the aims of the State are —

(1.) First of all, outward protection, which may just as well become needful against lifeless forces of nature or wild beasts as against men, consequently against other nations; although this case is the most frequent and important, for the worst enemy of man is man: *homo homini lupus*. Since, in consequence of this aim, nations always set up the principle, in words if not with deeds, that they wish to stand to each other in a purely defensive, never in an aggressive relation, they recognise *the law of nations*. This is at bottom nothing but natural law, in the only sphere of its practical activity that remains to it, between nation and nation, where it alone must

reign, because its stronger son, positive law, cannot assert itself, since it requires a judge and an executive. Accordingly the law of nations consists of a certain degree of morality in the dealings of nations with each other, the maintenance of which is a question of honour for mankind. The bar at which cases based on this law are tried is that of public opinion.

(2.) Protection within, thus protection of the members of a State against each other, consequently security of private right, by means of the maintenance of an honest state of things, which consists in this, that the concentrated forces of all protect each individual, from which arises an appearance as if all were honest, *i.e.*, just, thus as if no one wished to injure the others.

But, as is always the way in human affairs, the removal of one evil generally opens the way for a new one; thus the granting of that double protection introduces the need of a third, namely: (3.) Protection against the protector, *i.e.*, against him or those to whom the society has transferred the management of the protection, thus the guarantee of public right. This appears most completely attainable by dividing and separating from each other the threefold unity of the protective power, thus the legislature, the judicature, and the executive, so that each is managed by others, and independently of the rest. The great value, indeed the fundamental idea of the monarchy appears to me to lie in the fact that because men remain men one must be placed so high, and so much power, wealth, security, and absolute inviolability given him that there remains nothing for him to desire, to hope, and to fear for himself; whereby the egoism which dwells in him, as in every one, is annihilated, as it were, by neutralisation, and he is now able, as if he were no longer a man, to practise justice, and to keep in view no longer his own but only the public good. This is the source of the seemingly superhuman nature that everywhere accompanies royalty, and distinguishes it so infinitely from the mere presidency. Therefore it must also be hereditary, not elective; partly in order that no one may see his equal in the king; partly that the king himself may only be able to provide for his successors by caring for the welfare of the State, which is absolutely one with that of his family.

If other ends besides that of protection, here explained, are ascribed to the State, this may easily endanger the true end.

According to my explanation, the right of property arises only through the expenditure of labour upon things. This truth, which has already often been expressed, finds a noteworthy confirmation in the fact that it is asserted, even in a practical regard, in a declaration of the American ex-president, Quincey Adams, which is to be found in the *Quarterly Review* of 1840, No. 130; and also in French, in the "*Bibliothèque universelle de Genêve*," July 1840, No. 55. I will give it here in German (English of *Quarterly Review*): "There are moralists who have questioned the right of the Europeans to intrude upon the possessions of the aboriginals in any case, and under any limitations whatsoever; but have they maturely considered the whole subject? The Indian right of possession itself stands, with regard to the greatest part of the country, upon a *questionable* foundation. Their cultivated fields, their constructed habitations, a space of ample sufficiency for their subsistence, and whatever they had annexed of themselves by personal labour, was undoubtedly by the laws of nature theirs. But what is the right of a huntsman to the forest of a thousand miles over which he has accidentally ranged in quest of prey?" &c. In the same way, those who in our own day have seen occasion to combat communism with reasons (for example, the Archbishop of Paris, in his pastoral of June 1851) have always brought forward the argument that property is the result of work, as it were only embodied work. This is further evidence that the right of property can only be established by the application of work to things, for only in this respect does it find free recognition and make itself morally valid.

An entirely different kind of proof of the same truth is afforded by the moral fact that while the law punishes poaching just as severely as theft, and in many countries more severely, yet civil honour, which is irrevocably lost by the latter, is really not affected by the former; but the poacher, if he has been guilty of nothing else, is certainly tainted with a fault, but yet is not regarded, like the thief, as dishonourable and shunned by all. For the principles of civil honour rest upon moral and not upon mere positive law; but game is not an object upon which labour is bestowed, and thus also is not an object of a morally valid possession: the right to it is therefore entirely a positive one, and is not morally recognised.

According to my view, the principle ought to lie at the basis of criminal law that it is not really the man but only the deed which is punished, in order that it may not recur. The criminal is merely the subject in whom the

deed is punished, in order that the law in consequence of which the punishment is inflicted may retain its deterrent power. This is the meaning of the expression, "He is forfeited to the law." According to Kant's explanation, which amounts to a *jus talionis*, it is not the deed but the man that is punished. The penitentiary system also seeks not so much to punish the deed as the man, in order to reform him. It thereby sets aside the real aim of punishment, determent from the deed, in order to attain the very problematic end of reformation. But it is always a doubtful thing to attempt to attain two different ends by *one* means: how much more so if the two are in any sense opposite ends. Education is a benefit, punishment ought to be an evil; the penitentiary prison is supposed to accomplish both at once. Moreover, however large a share untutored ignorance, combined with outward distress, may have in many crimes, yet we dare not regard these as their principal cause, for innumerable persons living in the same ignorance and under absolutely similar circumstances commit no crimes. Thus the substance of the matter falls back upon the personal, moral character; but this, as I have shown in my prize essay on the freedom of the will, is absolutely unalterable. Therefore moral reformation is really not possible, but only determent from the deed through fear. At the same time, the correction of knowledge and the awakening of the desire to work can certainly be attained; it will appear what effect this can produce. Besides this, it appears to me, from the aim of punishment set forth in the text, that, when possible, the apparent severity of the punishment should exceed the actual: but solitary confinement achieves the reverse. Its great severity has no witnesses, and is by no means anticipated by any one who has not experienced it; thus it does not deter. It threatens him who is tempted to crime by want and misery with the opposite pole of human suffering, ennui: but, as Goethe rightly observes —

"When real affliction is our lot,
Then do we long for ennui."

The contemplation of it will deter him just as little as the sight of the palatial prisons which are built by honest men for rogues. If, however, it is desired that these penitentiary prisons should be regarded as educational institutions, then it is to be regretted that the entrance to them is only obtained by crimes, instead of which it ought to have preceded them.

That punishment, as Beccaria has taught, ought to bear a proper proportion to the crime does not depend upon the fact that it would be an

expiation of it, but rather on the fact that the pledge ought to be proportionate to the value of that for which it answers. Therefore every one is justified in demanding the pledge of the life of another as a guarantee for the security of his own life, but not for the security of his property, for which the freedom, and so forth, of another is sufficient pledge. For the security of the life of the citizens capital punishment is therefore absolutely necessary. Those who wish to abolish it should be answered, "First remove murder from the world, and then capital punishment ought to follow." It ought also to be inflicted for the clear attempt to murder just as for murder itself; for the law desires to punish the deed, not to revenge its consequences. In general the injury to be guarded against affords the right measure for the punishment which is to be threatened, but it does not give the moral baseness of the forbidden action. Therefore the law may rightly impose the punishment of imprisonment for allowing a flower-pot to fall from a window, or impose hard labour for smoking in the woods during the summer, and yet permit it in the winter. But to impose the punishment of death, as in Poland, for shooting an ure-ox is too much, for the maintenance of the species of ure-oxen may not be purchased with human life. In determining the measure of the punishment, along with the magnitude of the injury to be guarded against, we have to consider the strength of the motives which impel to the forbidden action. Quite a different standard of punishment would be established if expiation, retribution, *jus talionis*, were its true ground. But the criminal code ought to be nothing but a register of counter-motives for possible criminal actions: therefore each of these motives must decidedly outweigh the motives which lead to these actions, and indeed so much the more the greater the evil is which would arise from the action to be guarded against, the stronger the temptation to it, and the more difficult the conviction of the criminal; — always under the correct assumption that the will is not free, but determinable by motives; — apart from this it could not be got at at all. So much for the philosophy of law.

In my prize essay on the freedom of the will (p. 50 *seq.*) I have proved the originality and unalterableness of the inborn character, from which the moral content of the course of life proceeds. It is established as a fact. But in order to understand problems in their full extent it is sometimes necessary to oppose opposites sharply to each other. In this case, then, let one recall how incredibly great is the inborn difference between man and man, in a moral and in an intellectual regard. Here nobleness and wisdom;

there wickedness and stupidity. In one the goodness of the heart shines out of the eyes, or the stamp of genius is enthroned in his countenance. The base physiognomy of another is the impression of moral worthlessness and intellectual dulness, imprinted by the hands of nature itself, unmistakable and ineradicable; he looks as if he must be ashamed of existence. But to this outward appearance the inner being really corresponds. We cannot possibly assume that such differences, which transform the whole being of the man, and which nothing can abolish, which, further, in conflict with his circumstances, determine his course of life, could exist without guilt or merit on the part of those affected by them, and be merely the work of chance. Even from this it is evident that the man must be in a certain sense his own work. But now, on the other hand, we can show the source of these differences empirically in the nature of the parents; and besides this, the meeting and connection of these parents has clearly been the work of the most accidental circumstances. By such considerations, then, we are forcibly directed to the distinction between the phenomenon and the true being of things, which alone can contain the solution of that problem. The thing in itself only reveals itself by means of the forms of the phenomenon; therefore what proceeds from the thing in itself must yet appear in those forms, thus also in the bonds of causality. Accordingly it will present itself to us here as a mysterious and incomprehensible guidance of things, of which the external empirical connection would be the mere tool. Yet all that happens appears in this empirical connection introduced by causes, thus necessarily and determined from without, while its true ground lies in the inner nature of what thus manifests itself. Certainly we can here see the solution of the problem only from afar, and when we reflect upon it we fall into an abyss of thought — as Hamlet very truly says, “thoughts beyond the reaches of our souls.” In my essay in the first volume of the Parerga “On the Appearance of Intention in the Fate of Individuals” I have set forth my thoughts upon this mysterious guidance of things, a guidance which indeed can only be conceived symbolically.

In § 14 of my prize essay on the foundation of morals there will be found an exposition of egoism, as regards its nature; and the following attempt to discover its root may be looked upon as supplementary to that paragraph. Nature itself contradicts itself directly, according as it speaks from the individual or the universal, from within or from without, from the centre or the periphery. It has its centre in every individual; for each individual is the

whole will to live. Therefore, even if this individual is only an insect or a worm, nature itself speaks out of it thus: "I alone am all in all: in my maintenance everything is involved; the rest may perish, it is really nothing." So speaks nature from the *particular* standpoint, thus from the point of view of self-consciousness, and upon this depends the egoism of every living thing. On the other hand, from the *universal* point of view, — which is that of the *consciousness of other things*, that of objective knowledge, which for the moment looks away from the individual with whom the knowledge is connected, — from without then, from the periphery nature speaks thus: "The individual is nothing, and less than nothing. I destroy millions of individuals every day, for sport and pastime: I abandon their fate to the most capricious and wilful of my children, chance, who harasses them at pleasure. I produce millions of new individuals every day, without any diminution of my productive power; just as little as the power of a mirror is exhausted by the number of reflections of the sun, which it casts on the wall one after another. The individual is nothing." Only he who knows how to really reconcile and eliminate this patent contradiction of nature has a true answer to the question as to the perishableness and imperishableness of his own self. I believe I have given, in the first four chapters of this fourth book of the supplements, an adequate introduction to such knowledge. What is said above may further be illustrated in the following manner. Every individual, when he looks within, recognises in his nature, which is his will, the thing in itself, therefore that which everywhere alone is real. Accordingly he conceives himself as the kernel and centre of the world, and regards himself as of infinite importance. If, on the other hand, he looks without, then he is in the province of the idea the mere phenomenon, where he sees himself as an individual among an infinite number of other individuals, accordingly as something very insignificant, nay, vanishing altogether. Consequently every individual, even the most insignificant, every I, when regarded from within, is all in all; regarded from without, on the other hand, he is nothing, or at least as good as nothing. Hence upon this depends the great difference between what each one necessarily is in his own eyes and what he is in the eyes of others, consequently the egoism with which every one reproaches every one else.

In consequence of this egoism our fundamental error of all is this, that with reference to each other we are reciprocally not I. On the other hand, to

be just, noble, and benevolent is nothing else than to translate my metaphysics into actions. To say that time and space are mere forms of our knowledge, not conditions of things in themselves, is the same as to say that the doctrine of metempsychosis, “Thou shalt one day be born as him whom thou now injurest, and in thy turn shalt suffer like injury,” is identical with the formula of the Brahmans, which has frequently been mentioned, *Tat twam asi*, “This thou art.” All true virtue proceeds from the immediate and intuitive knowledge of the metaphysical identity of all beings, which I have frequently shown, especially in § 22 of my prize essay on the foundation of morals. But just on this account it is not the result of a special pre-eminence of intellect; on the contrary, even the weakest intellect is sufficient to see through the *principium individuationis*, which is what is required in this matter. Accordingly we may find the most excellent character even in the case of a very weak understanding. And further, the excitement of our sympathy is accompanied by no exertion of our intellect. It rather appears that the requisite penetration of the *principium individuationis* would be present in every one if it were not that the *will* opposes this, and by virtue of its immediate mysterious and despotic influence upon the intellect generally prevents it from arising; so that ultimately all guilt falls back upon the *will*, as indeed is in conformity with the fact.

The doctrine of metempsychosis, touched on above, deviates from the truth merely through the circumstance that it transfers to the future what already is now. It makes my true inner nature exist in others only after my death, while, according to the truth, it already lives in them now, and death merely removes the illusion on account of which I am not aware of this; just as an innumerable host of stars constantly shine above our heads, but only become visible to us when the one sun near the earth has set. From this point of view my individual existence, however much, like that sun, it may outshine everything, appears ultimately only as a hindrance which stands between me and the knowledge of the true extent of my being. And because every individual, in his knowledge, is subject to this hindrance, it is just individuation that keeps the will to live in error as to its own nature; it is the Mâyâ of Brahmanism. Death is a refutation of this error, and abolishes it. I believe that at the moment of death we become conscious that it is a mere illusion that has limited our existence to our person. Indeed empirical traces of this may be found in several states which are related to death by the abolition of the concentration of consciousness in the brain, among which

the magnetic sleep is the most prominent; for in it, if it reaches a high degree, our existence shows itself through various symptoms, beyond our persons and in other beings, most strikingly by direct participation in the thoughts of another individual, and ultimately even by the power of knowing the absent, the distant, and even the future, thus by a kind of omnipresence.

Upon this metaphysical identity of the will, as the thing in itself, in the infinite multiplicity of its phenomena, three principal phenomena depend, which may be included under the common name of sympathies: (1) *sympathy proper*, which, as I have shown, is the basis of justice and benevolence, *caritas*; (2) *sexual love*, with capricious selection, *amor*, which is the life of the species, that asserts its precedence over that of the individual; (3) *magic*, to which animal magnetism and sympathetic cures also belong. Accordingly *sympathy* may be defined as the empirical appearance of the metaphysical identity of the will, through the physical multiplicity of its phenomena, whereby a connection shows itself which is entirely different from that brought about by means of the forms of the phenomenon which we comprehend under the principle of sufficient reason.

Chapter XLVIII.[44]On The Doctrine Of The Denial Of The Will To Live.

Man has his existence and being either *with* his will, *i.e.*, his consent, or *without* this; in the latter case an existence so embittered by manifold and insupportable sufferings would be a flagrant injustice. The ancients, especially the Stoics, also the Peripatetics and Academics, strove in vain to prove that virtue sufficed to make life happy. Experience cried out loudly against it. What really lay at the foundation of the efforts of these philosophers, although they were not distinctly conscious of it, was the assumed *justice* of the thing; whoever was without guilt ought to be free from suffering, thus happy. But the serious and profound solution of the problem lies in the Christian doctrine that works do not justify. Accordingly a man, even if he has practised all justice and benevolence, consequently the αγαθον, *honestum*, is yet not, as Cicero imagines, *culpa omni carens* (*Tusc.*, v. i.); but *el delito mayor del hombre es haber nacido* (the greatest guilt of man is that he was born), as Calderon, illuminated by Christianity, has expressed it with far profounder knowledge than these wise men. Therefore that man comes into the world already tainted with guilt can appear absurd only to him who regards him as just then having arisen out of nothing and as the work of another. In consequence of *this* guilt, then, which must therefore have proceeded from his will, man remains rightly exposed to physical and mental suffering, even if he has practised all those virtues, thus is not happy. This follows from the *eternal justice* of which I have spoken in § 63 of the first volume. That, however, as St. Paul (Rom. iii. 21), Augustine, and Luther teach, works cannot justify, inasmuch as we all are and remain essentially sinners, ultimately rests upon the fact that, because *operari sequitur esse*, if we acted as we ought, we would necessarily be as we ought. But then we would require no *salvation* from our present condition, which not only Christianity but also Brahmanism and Buddhism (under the name which is expressed in English by *final emancipation*) present as the highest goal, *i.e.*, we would not need to become something quite different from, nay, the very opposite of what we are. Since, however, we are what we ought not to be, we also necessarily do what we ought not to do. Therefore we need a complete transformation of

our mind and nature; *i.e.*, the new birth, as the result of which salvation appears. Although the guilt lies in action, *operari*, yet the root of the guilt lies in our *essentia et existentia*, for out of these the *operari* necessarily proceeds, as I have shown in the prize essay on the freedom of the will. Accordingly our one true sin is really original sin. Now the Christian myth makes original sin first arise after man came into existence, and for this purpose ascribes to him, *per impossibile*, a free will. It does this, however, simply as myth. The inmost kernel and spirit of Christianity is identical with that of Brahmanism and Buddhism; they all teach a great guilt of the human race through its existence itself, only that Christianity does not proceed directly and frankly like these more ancient religions: thus does not make the guilt simply the result of existence itself, but makes it arise through the act of the first human pair. This was only possible under the fiction of a *liberum arbitrium indifferentiæ*, and only necessary on account of the Jewish fundamental dogma, in which that doctrine had here to be implanted. Because, according to the truth, the coming into existence of man himself is the act of his free will, and accordingly one with the fall, and therefore the original sin, of which all other sins are the result, appeared already with the *essentia* and *existentia* of man; but the fundamental dogma of Judaism did not admit of such an explanation. Thus Augustine taught, in his books *De libero arbitrio*, that only as Adam before the fall was man guiltless and possessed of a free will, but for ever after is involved in the necessity of sin. The law, ὁ νομος, in the Biblical sense, always demands that we shall change our doing, while our being remains unchanged. But because this is impossible, Paul says that no man is justified by the law; only the new birth in Jesus Christ, in consequence of the work of grace, on account of which a new man arises and the old man is abolished (*i.e.*, a fundamental change of mind or conversion), can transfer us from the state of sinfulness into that of freedom and salvation. This is the Christian myth with reference to ethics. But certainly the Jewish theism, upon which it was grafted, must have received wonderful additions to adapt itself to that myth. In it the fable of the fall presented the only place for the graft of the old Indian stem. It is to be attributed just to that forcibly surmounted difficulty that the Christian mysteries have received such an extraordinary appearance, conflicting with the ordinary understanding, which makes proselytising more difficult, and on account of which, from incapacity to comprehend their profound meaning, Pelagianism, or at the present day

Rationalism, rises against them, and seeks to explain them away, but thereby reduces Christianity to Judaism.

But to speak without myth: so long as our will is the same, our world can be no other than it is. It is true all wish to be delivered from the state of suffering and death; they would like, as it is expressed, to attain to eternal blessedness, to enter the kingdom of heaven, only not upon their own feet; they would like to be carried there by the course of nature. That, however, is impossible. Therefore nature will never let us fall and become nothing; but yet it can lead us nowhere but always again into nature. Yet how questionable a thing it is to exist as a part of nature every one experiences in his own life and death. Accordingly existence is certainly to be regarded as an erring, to return from which is salvation: it also bears this character throughout. It is therefore conceived in this manner by the ancient Samana religions, and also, although indirectly, by real and original Christianity. Even Judaism itself contains at least in the fall (this its redeeming feature) the germ of such a view. Only Greek paganism and Islamism are entirely optimistic: therefore in the former the opposite tendency had to find expression at least in tragedy; but in Islamism, which is the worst, as it is the most modern, of all religions, it appeared as Sufism, that very beautiful phenomenon, which is completely of Indian spirit and origin, and has now continued for upwards of a thousand years. Nothing can, in fact, be given as the end of our existence but the knowledge that we had better not be. This, however, is the most important of all truths, which must therefore be expressed, however great the contrast in which it stands with the European manner of thought of the present day. On the other hand, in the whole of non-Mohammedan Asia it is the most universally recognised fundamental truth, to-day as much as three thousand years ago.

If now we consider the will to live as a whole and objectively, we have, in accordance with what has been said, to think of it as involved in an illusion, to escape from which, thus to deny its whole existing endeavour, is what all religions denote by self-renunciation, *abnegatio sui ipsius*; for the true self is the will to live. The moral virtues, thus justice and benevolence, since if they are pure they spring, as I have shown, from the fact that the will to live, seeing through the *principium individuationis*, recognises itself in all its manifestations, are accordingly primarily a sign, a symptom, that the self-manifesting will is no longer firmly held in that illusion, but the disillusion already begins to take place; so that one might metaphorically

say it already flaps its wings to fly away from it. Conversely, injustice, wickedness, cruelty are signs of the opposite, thus of the deep entanglement in that illusion. Secondly, however, these virtues are a means of advancing self-renunciation, and accordingly the denial of the will to live. For true integrity, inviolable justice, this first and most important of cardinal virtues, is so hard a task that whoever professes it unconditionally and from the bottom of his heart has to make sacrifices that soon deprive life of the sweetness which is demanded to make it enjoyable, and thereby turn away the will from it, thus lead to resignation. Yet just what makes integrity honourable is the sacrifices which it costs; in trifles it is not admired. Its nature really consists in this, that the just man does not throw upon others, by craft or force, the burdens and sorrows which life brings with it, as the unjust man does, but bears himself what falls to his lot; and thus he has to bear the full burden of the evil imposed upon human life, undiminished. Justice thereby becomes a means of advancing the denial of the will to live, for want and suffering, those true conditions of human life, are its consequence, and these lead to resignation. Still more quickly does the virtue of benevolence, *caritas*, which goes further, lead to the same result; for on account of it one takes over even the sufferings which originally fell to the lot of others, therefore appropriates to oneself a larger share of these than in the course of things would come to the particular individual. He who is inspired with this virtue has recognised his own being in all others. And thereby he identifies his own lot with that of humanity in general; but this is a hard lot, that of care, suffering, and death. Whoever, then, by renouncing every accidental advantage, desires for himself no other lot than that of humanity in general cannot desire even this long. The clinging to life and its pleasures must now soon yield, and give place to a universal renunciation; consequently the denial of the will will take place. Since now, in accordance with this, poverty, privation, and special sufferings of many kinds are introduced simply by the perfect exercise of the moral virtues, asceticism in the narrowest sense, thus the surrender of all possessions, the intentional seeking out of what is disagreeable and repulsive, self-mortification, fasts, the hair shirt, and the scourge — all this is rejected by many, and perhaps rightly, as superfluous. Justice itself is the hair shirt that constantly harasses its owner and the charity that gives away what is needed, provides constant fasts.[45] Just on this account Buddhism is free from all strict and excessive asceticism, which plays a large part in Brahmanism, thus from intentional

self-mortification. It rests satisfied with the celibacy, voluntary poverty, humility, and obedience of the monks, with abstention from animal food, as also from all worldliness. Since, further, the goal to which the moral virtues lead is that which is here pointed out, the Vedanta philosophy[46] rightly says that after the entrance of true knowledge, with entire resignation in its train, thus the new birth, then the morality or immorality of the past life is a matter of indifference, and uses here also the saying so often quoted by the Brahmans: "*Finditur nodus cordis, dissolvuntur omnes dubitationes, ejusque opera evanescunt, viso supremo illo*" (*Sancara, sloca 32*).

Now, however objectionable this view may be to many, to whom a reward in heaven or a punishment in hell is a much more satisfactory explanation of the ethical significance of human action, just as the good Windischmann rejects that doctrine, while he expounds it, yet whoever is able to go to the bottom of the matter will find that in the end it agrees with that Christian doctrine especially urged by Luther, that it is not works but only the faith which enters through the work of grace, that saves us, and that therefore we can never be justified by our deeds, but can only obtain the forgiveness of our sins through the merits of the Mediator. It is indeed easy to see that without such assumptions Christianity would have to teach infinite punishment for all, and Brahmanism endless re-births for all, thus no salvation would be reached by either. The sinful works and their consequences must be annulled and annihilated, whether by extraneous pardon or by the entrance of a better knowledge; otherwise the world could hope for no salvation; afterwards, however, they become a matter of indifference. This is also the μετανοια και αφεσις ἁμαρτιων, the announcement of which the risen Christ exclusively imposes upon His Apostles as the sum of their mission (Luke xxiv. 47). The moral virtues are really not the ultimate end, but only a step towards it. This step is signified in the Christian myth by the eating of the tree of the knowledge of good and evil, with which moral responsibility enters, together with original sin. The latter itself is in truth the assertion of the will to live: the denial of the will to live, in consequence of the appearance of a better knowledge, is, on the other hand, salvation. Between these two, then, lies the sphere of morality; it accompanies man as a light upon his path from the assertion to the denial of the will, or, mythically, from original sin to salvation through faith in the mediation of the incarnate God (Avatar); or, according to the teaching of the

Vedas, through all re-births, which are the consequence of the works in each case, until right knowledge appears, and with it salvation (final emancipation), Mokscha, *i.e.*, reunion with Brahma. The Buddhists, however, with perfect honesty, only indicate the matter negatively, by Nirvana, which is the negation of this world, or of Sansara. If Nirvana is defined as nothing, this only means that the Sansara contains no single element which could assist the definition or construction of Nirvana. Just on this account the Jainas, who differ from the Buddhists only in name, call the Brahmans who believe in the Vedas Sabdapramans, a nickname which is meant to signify that they believe upon hearsay what cannot be known or proved ("Asiat. Researches," vol. vi. P. 474).

When certain ancient philosophers, such as Orpheus, the Pythagoreans, and Plato (*e.g.*, in the "Phædo," pp. 151, 183 *seq.*, Bip.; and see *Clem. Alex. strom.*, iii. p. 400 *seq.*), just like the Apostle Paul, lament the union of soul and body, and desire to be freed from it, we understand the real and true meaning of this complaint, since we have recognised, in the second book, that the body is the will itself, objectively perceived as a phenomenon in space.

In the hour of death it is decided whether the man returns into the womb of nature or belongs no more to nature at all, but —— —— —— : for this opposite we lack image, conception, and word, just because these are all taken from the objectification of the will, therefore belong to this, and consequently can in no way express the absolute opposite of it, which accordingly remains for us a mere negation. However, the death of the individual is in each case the unweariedly repeated question of nature to the will to live, "Hast thou enough? Wilt thou escape from me?" In order that it may occur often enough, the individual life is so short. In this spirit are conceived the ceremonies, prayers, and exhortations of the Brahmans at the time of death, as we find them preserved in the Upanischad in several places; and so also are the Christian provisions for the suitable employment of the hour of death by means of exhortation, confession, communion, and extreme unction: hence also the Christian prayers for deliverance from sudden death. That at the present day it is just this that many desire only proves that they no longer stand at the Christian point of view, which is that of the denial of the will to live, but at that of its assertion, which is the heathen point of view.

But he will fear least to become nothing in death who has recognised that he is already nothing now, and who consequently no longer takes any share in his individual phenomenon, because in him knowledge has, as it were, burnt up and consumed the will, so that no will, thus no desire for individual existence, remains in him any more.

Individuality inheres indeed primarily in the intellect; and the intellect, reflecting the phenomenon, belongs to the phenomenon, which has the *principium individuationis* as its form. But it inheres also in the will, inasmuch as the character is individual: yet the character itself is abolished in the denial of the will. Thus individuality inheres in the will only in its assertion, not in its denial. Even the holiness which is connected with every purely moral action depends upon the fact that such an action ultimately springs from the immediate knowledge of the numerical identity of the inner nature of all living things.[47] But this identity only really exists in the condition of the denial of the will (Nirvana), for the assertion of the will (Sansara) has for its form the phenomenal appearance of it in multiplicity. Assertion of the will to live, the phenomenal world, the diversity of all beings, individuality, egoism, hatred, wickedness, all spring from *one* root; and so also, on the other hand, do the world as thing in itself, the identity of all beings, justice, benevolence, the denial of the will to live. If now, as I have sufficiently proved, even the moral virtues spring from the consciousness of that identity of all beings, but this lies, not in the phenomenon, but only in the thing in itself, in the root of all beings, the moral action is a momentary passing through the point, the permanent return to which is the denial of the will to live.

It follows, as a deduction from what has been said, that we have no ground to assume that there are more perfect intelligences than that of human beings. For we see that even this degree of intelligence is sufficient to impart to the will that knowledge in consequence of which it denies and abolishes itself, upon which the individuality, and consequently the intelligence, which is merely a tool of individual, and therefore animal nature, perish. This will appear to us less open to objection if we consider that we cannot conceive even the most perfect intelligences possible, which for this end we may experimentally assume, existing through an endless time, which would be much too poor to afford them constantly new objects worthy of them. Because the nature of all things is at bottom one, all knowledge of them is necessarily tautological. If now this nature once

becomes comprehended, as by those most perfect intelligences it soon would be comprehended, what would then remain but the wearisomeness of mere repetition through an infinite time? Thus from this side also we are pointed to the fact that the end of all intelligence can only be reaction upon the will; since, however, all willing is an error, it remains the last work of intelligence to abolish the willing, whose ends it had hitherto served. Accordingly even the most perfect intelligence possible can only be a transition step to that to which no knowledge can ever extend: indeed such an intelligence can, in the nature of things, only assume the position of the moment of the attainment of perfect insight.

In agreement with all these considerations, and also with what is proved in the second book as to the origin of knowledge in the will, the *assertion* of which it reflects in fulfilling the sole function of knowledge, that of being serviceable to the ends of the will, while true salvation lies in its *denial*, we see all religions at their highest point pass over into mysticism and mysteries, *i.e.*, into darkness and veiled obscurity, which for knowledge signify merely an empty spot, the point where knowledge necessarily ceases; therefore for thought this can only be expressed by negations, but for sense perception it is indicated by symbolical signs; in temples by dim light and silence; in Brahmanism indeed by the required suspension of all thought and perception for the sake of sinking oneself profoundly in the grounds of one's own being, mentally pronouncing the mysterious Oum.[48] Mysticism in the widest sense is every guidance to the immediate consciousness of that to which neither perception nor conception, thus in general no knowledge extends. The mystic is thus opposed to the philosopher by the fact that he begins from within, while the philosopher begins from without. The mystic starts from his inner, positive, individual experience, in which he finds himself to be the eternal and only being, &c. But nothing of this is communicable except the assertions which one has to accept upon his word; consequently he cannot convince. The philosopher, on the other hand, starts from what is common to all, from the objective phenomenon which lies before all, and from the facts of consciousness as they are present in all. His method is therefore reflection upon all this, and combination of the data given in it: accordingly he can convince. He ought therefore to beware of falling into the way of the mystics, and, for example, by the assertion of intellectual intuitions or pretended immediate apprehensions of the reason, to seek to make a vain show of positive

knowledge of that which is for ever inaccessible to all knowledge, or at the most can be indicated by means of a negation. The value and worth of philosophy lies in the fact that it rejects all assumptions which cannot be established, and takes as its data only what can be certainly proved in the world given in external perception, in the forms of apprehension of this world, which are constitutive of our intellect, and in the consciousness of one's own self which is common to all. Therefore it must remain cosmology, and cannot become theology. Its theme must limit itself to the world; to express in all aspects what this *is*, what it is in its inmost nature, is all that it can honestly achieve. Now it answers to this that my system when it reaches its highest point assumes a *negative* character, thus ends with a negation. It can here speak only of what is denied, given up: but what is thereby won, what is laid hold of, it is obliged (at the conclusion of the fourth book) to denote as nothing, and can only add the consolation that it is merely a relative, not an absolute nothing. For if something is none of all the things which we know, it is certainly for us, speaking generally, nothing. But it does not yet follow from this that it is absolutely nothing, that from every possible point of view and in every possible sense it must be nothing, but only that we are limited to a completely negative knowledge of it, which may very well lie in the limitation of our point of view. Now it is just here that the mystic proceeds positively, and therefore it is just from this point that nothing but mysticism remains. However, any one who wishes this kind of supplement to the negative knowledge to which alone philosophy can guide him will find it in its most beautiful and richest form in the Oupnekhat, then also in the Enneads of Plotinus, in Scotus Erigena, in passages of Jakob Böhm, but especially in the marvellous work of Madame de Guion, *Les Torrens*, and in Angelus Silesius; finally also in the poems of the Sufis, of which Tholuk has given us a collection translated into Latin, and another translated into German, and in many other works. The Sufis are the Gnostics of Islam. Hence Sadi denotes them by a word which may be translated "full of insight." Theism, calculated with reference to the capacity of the multitude, places the source of existence without us, as an object. All mysticism, and so also Sufism, according to the various degrees of its initiation, draws it gradually back within us, as the subject, and the adept recognises at last with wonder and delight that he is it himself. This procedure, common to all mysticism, we find not only expressed by Meister Eckhard, the father of German mysticism, in the form of a precept for the

perfect ascetic, “that he seek not God outside himself” (Eckhard’s works, edited by Pfeiffer, vol. i. p. 626), but also very naïvely exhibited by Eckhard’s spiritual daughter, who sought him out, when she had experienced that conversion in herself, to cry out joyfully to him, “Sir, rejoice with me, I have become God” (*loc. cit.*, p. 465). The mysticism of the Sufis also expresses itself throughout precisely in accordance with this spirit, principally as a revelling in the consciousness that one is oneself the kernel of the world and the source of all existence, to which all returns. Certainly there also often appears the call to surrender all volition as the only way in which deliverance from individual existence and its suffering is possible, yet subordinated and required as something easy. In the mysticism of the Hindus, on the other hand, the latter side comes out much more strongly, and in Christian mysticism it is quite predominant, so that pantheistic consciousness, which is essential to all mysticism, here only appears in a secondary manner, in consequence of the surrender of all volition, as union with God. Corresponding to this difference of the conception, Mohammedan mysticism has a very serene character, Christian mysticism a gloomy and melancholy character, while that of the Hindus, standing above both, in this respect also holds the mean.

Quietism, *i.e.*, surrender of all volition, asceticism, *i.e.*, intentional mortification of one’s own will, and mysticism, *i.e.*, consciousness of the identity of one’s own nature with that of all things or with the kernel of the world, stand in the closest connection; so that whoever professes one of them is gradually led to accept the others, even against his intention. Nothing can be more surprising than the agreement with each other of the writers who present these doctrines, notwithstanding the greatest difference of their age, country, and religion, accompanied by the firm certainty and inward confidence with which they set forth the permanence of their inner experience. They do not constitute a *sect*, which adheres to, defends, and propagates a favourite dogma once laid hold of; indeed the Indian, Christian, and Mohammedan mystics, quietists, and ascetics are different in every respect, except the inner significance and spirit of their teaching. A very striking example of this is afforded by the comparison of the *Torrens* of Madame de Guion with the teaching of the Vedas, especially with the passage in the Oupnekhat, vol. i. p. 63, which contains the content of that French work in the briefest form, but accurately and even with the same images, and yet could not possibly have been known to Madame de Guion

in 1680. In the "*Deutschen Theologie*" (the only unmutilated edition, Stuttgart, 1851) it is said in chapters 2 and 3 that both the fall of the devil and that of Adam consisted in the fact that the one as the other ascribed to himself the I and me, the mine and to me, and on p. 89 it is said: "In true love there remains neither I nor me, mine, to me, thou, thine, and the like." Now, corresponding to this, it is said in the "Kural," from the Tamilian by Graul, p. 8: "The passion of the mine directed outwardly, and that of the I directed inwardly, cease" (*cf.* ver. 346). And in the "Manual of Buddhism" by Spence Hardy, p. 258, Buddha says: "My disciples reject the thoughts I am this, or this is mine." In general, if we look away from the forms which are introduced by external circumstances and go to the bottom of the matter, we will find that Sakya Muni and Meister Eckhard teach the same; only that the former dared to express his thoughts directly, while the latter is obliged to clothe them in the garments of the Christian myth and adapt his expressions to this. He carries this, however, so far that with him the Christian myth has become little more than a symbolical language, just as the Hellenic myth became for the Neo-Platonists: he takes it throughout allegorically. In the same respect it is worth noticing that the transition of St. Francis from prosperity to the mendicant life is similar to the still greater step of Buddha Sakya Muni from prince to beggar, and that, corresponding to this, the life of St. Francis, and also the order he founded, was just a kind of Sannyasiism. Indeed it deserves to be mentioned that his relationship with the Indian spirit appears also in his great love for the brutes and frequent intercourse with them, when he always calls them his sisters and brothers; and his beautiful Cantico also bears witness to his inborn Indian spirit by the praise of the sun, the moon, the stars, the wind, the water, the fire, and the earth.[49]

Even the Christian quietists must often have had little or no knowledge of each other; for example, Molinos and Madame de Guion of Tauler and the "*Deutsche Theologie*," or Gichtel of the former. In any case, the great difference of their culture, in that some of them, like Molinos, were learned, others, like Gichtel and many more, were the reverse, has no essential influence upon their teaching. Their great internal agreement, along with the firmness and certainty of their utterances, proves all the more that they speak from real inward experience, from an experience which certainly is not accessible to all, but is possessed only by a few favoured individuals, and therefore has received the name of the work of grace, the reality of

which, however, for the above reasons, is not to be doubted. But in order to understand all this one must read the mystics themselves, and not be contented with second-hand reports of them; for every one must himself be comprehended before one judges concerning him. Thus to become acquainted with quietism I specially recommend Meister Eckhard, the "*Deutsche Theologie*," Tauler, Madame de Guion, Antoinette Bourignon, the English Bunyan, Molinos[50] and Gichtel. In the same way, as practical proofs and examples of the profound seriousness of asceticism, the life of Pascal, edited by Reuchlin, together with his history of the Port-Royal, and also the *Histoire de Sainte Elisabeth, par le comte de Montalembert*, and *La vie de Rancé, par Chateaubriand*, are very well worth reading, but yet by no means exhaust all that is important in this class. Whoever has read such writings, and compared their spirit with that of ascetism and quietism as it runs through all works of Brahmanism and Buddhism, and speaks in every page, will admit that every philosophy, which must in consistency reject that whole mode of thought, which it can only do by explaining the representatives of it to be either impostors or mad-men, must just on this account necessarily be false. But all European systems, with the exception of mine, find themselves in this position. Truly it must be an extraordinary madness which, under the most widely different circumstances and persons possible, spoke with such agreement, and, moreover, was raised to the position of a chief doctrine of their religion, by the most ancient and numerous peoples of the earth, something like three-fourths of all the inhabitants of Asia. But no philosophy can leave the theme of quietism and asceticism undecided if the question is proposed to it; because this theme is, in its matter, identical with that of all metaphysics and ethics. Here then is a point upon which I expect and desire that every philosophy, with its optimism, should declare itself. And if, in the judgment of contemporaries, the paradoxical and unexampled agreement of my philosophy with quietism and asceticism appears as an open stumbling-block, I, on the contrary, see just in that agreement a proof of its sole correctness and truth, and also a ground of explanation of why it is ignored and kept secret by the *Protestant* universities.

For not only the religions of the East, but also true Christianity, has throughout that ascetic fundamental character which my philosophy explains as the denial of the will to live; although Protestantism, especially in its present form, seeks to conceal this. Yet even the open enemies of

Christianity who have appeared in the most recent times have ascribed to it the doctrines of renunciation, self-denial, perfect chastity, and, in general, mortification of the will, which they quite correctly denote by the name of the "*anti-cosmic tendency*," and have fully proved that such doctrines are essentially proper to original and genuine Christianity. In this they are undeniably right. But that they set up this as an evident and patent reproach to Christianity, while just here lies its profoundest truth, its high value, and its sublime character, — this shows an obscuring of the mind, which can only be explained by the fact that these men's minds, unfortunately like thousands more at the present day in Germany, are completely spoiled and distorted by the miserable Hegelism, that school of dulness, that centre of misunderstanding and ignorance, that mind-destroying, spurious wisdom, which now at last begins to be recognised as such, and the veneration of which will soon be left to the Danish Academy, in whose eyes even that gross charlatan is a *summus philosophus*, for whom it takes the field: —

"*Car ils suivront la créance et estude,*
De l'ignorante et sotte multitude,
Dont le plus lourd sera reça pour juge."
— Rabelais.

In any case, the ascetic tendency is unmistakable in the genuine and original Christianity as it developed in the writings of the Church Fathers from its kernel in the New Testament; it is the summit towards which all strives upwards. As its chief doctrine we find the recommendation of genuine and pure celibacy (this first and most important step in the denial of the will to live), which is already expressed in the New Testament.[51] Strauss also, in his "Life of Jesus" (vol i. p. 618 of the first edition), says, with reference to the recommendation of celibacy given in Matt. xix. 11 *seq.*, "That the doctrine of Jesus may not run counter to the ideas of the present day, men have hastened to introduce surreptitiously the thought that Jesus only praised celibacy with reference to the circumstances of the time, and in order to leave the activity of the Apostles unfettered; but there is even less indication of this in the context than in the kindred passage, 1 Cor. vii. 25 *seq.*; but we have here again one of the places where *ascetic principles*, such as prevailed among the Essenes, and probably still more widely among the Jews, appear in the teaching of Jesus also." This ascetic tendency appears more decidedly later than at the beginning, when Christianity, still seeking adherents, dared not pitch its demands too high; and by the

beginning of the third century it is expressly urged. Marriage, in genuine Christianity, is merely a compromise with the sinful nature of man, as a concession, something allowed to those who lack strength to aspire to the highest, an expedient to avoid greater evil: in this sense it receives the sanction of the Church in order that the bond may be indissoluble. But celibacy and virginity are set up as the higher consecration of Christianity through which one enters the ranks of the elect. Through these alone does one attain the victor's crown, which even at the present day is signified by the wreath upon the coffin of the unmarried, and also by that which the bride lays aside on the day of her marriage.

A piece of evidence upon this point, which certainly comes to us from the primitive times of Christianity, is the pregnant answer of the Lord, quoted by Clemens Alexandrinus (*Strom.* iii. 6 *et* 9) from the Gospel of the Egyptians: "Τῃ Σαλωμῃ ὁ κυριος πυνθανομενῃ, μεχρι ποτε θανατος ισχυσει; μεχρις αν ειπεν, ὑμεις, αἱ γυναικες, τικτετε" (*Salomæ interroganti quousque vigebit mors?Dominus guoadlusque inguit vos, mulieres, paritis*). "Τουτ᾽ εστι, μεχρις αν αἱ επιθυμιαι ενεργωσι" (*Hoc est, quamdiu operabuntur cupiditates*), adds Clement, c. 9, with which he at once connects the famous passage, Rom. v. 12. Further on, c. 13, he quotes the words of Cassianus: "Πυνθανομενης της Σαλωμης, ποτε γνωσθησεται τα περι ὡν ηρετο, εφη ὁ κυριος, Ὀταν της αισχυνς ενδυμα πατησετε, και ὁταν γενηται τα δυο ἑν, και το αρρεν μετα της θηλειας ουτε αρρεν, ουτε θηλυ" (*Cum interrogaret Salome, quando cognoscentur ea, de quibus interrogabat, ait Dominus: quando pudoris indumentum conculcaveritis, et quando duo facto fuerint unum, et masculum cum fæmina nec masculum, nec fæminium*), *i.e.*, when she no longer needs the veil of modesty, since all distinction of sex will have disappeared.

With regard to this point the heretics have certainly gone furthest: even in the second century the Tatianites or Encratites, the Gnostics, the Marcionites, the Montanists, Valentinians, and Cassians; yet only because with reckless consistency they gave honour to the truth, and therefore, in accordance with the spirit of Christianity, they taught perfect continence; while the Church prudently declared to be heresy all that ran counter to its far-seeing policy. Augustine says of the Tatianites: "*Nuptias damnant, atque omnino pares eas fornicationibus aliisque corruptionibus faciunt: nec recipiunt in suum numerum conjugio utentem, sive marem, sive fæminam.*

Non vescunlur carnibus, easque abominantur.” (*De hæresi ad quod vult Deum. hær.*, 25.) But even the orthodox Fathers look upon marriage in the light indicated above, and zealously preach entire continence, the ἁγνεια. Athanasius gives as the cause of marriage: “Ὅτι υποπιπτοντες εσμεν τῃ του προπατορος καταδικῃ ... επειδη ὁ προηγουμενος σκοπος του θεου ην, το μη δια γαμου γενεσθαι ἡμας και φθορας; ἡ δε παραβασις της εντολης του γαμον εισηγαγεν δια το ανομησαι τον Αδαμ.” (*Quia subjacemus condemnationi propatoris nostri; ... nam finis, a Deo prælatus, erat, nos non per nuptias et corruptionem fieri: sed transgressio mandati nuptias introduxit, propter legis violationem Adæ. — Exposit. in psalm.* 50). Tertullian calls marriage *genus mali inferioris, ex indulgentia ortum* (*De pudicitia*, c. 16) and says: “*Matrimonium et stuprum est commixtio carnis; scilicet cujus concupiscentiam dominus stupro adæquavit. Ergo, inguis, jam et primas, id est unas nuptias destruis? Nec immerito: quoniam et ipsæ ex eo constant, quod est stuprum*” (*De exhort. castit.*, c. 9). Indeed, Augustine himself commits himself entirely to this doctrine and all its results, for he says: “*Novi quosdam, qui murmurent: quid, si, inquiunt, omnes velint ab omni concubitu abstinere, unde subsistet genus humanum? Utinam omnes hoc vellent! dumtaxat in caritate, de corde puro et conscientia bona, et fide non ficta: multo citius Dei civitas compleretur, ut acceleraretur terminus mundi*” (*De bono conjugali*, c. 10). And again: “*Non vos ab hoc studio, quo multos ad imitandum vos excitatis, frangat querela vanorum, qui dicunt: quomodo subsistet genus humanum, si omnes fuerint continentes? Quasi propter aliud retardetur hoc seculum, nisi ut impleatur prædestinatus numerus ille sanctorum, quo citius impleto, profecto nec terminus seculi differetur*” (*De bono individuitatis*, c. 23). One sees at once that he identifies salvation with the end of the world. The other passages in the works of Augustine which bear on this point will be found collected in the “*Confessio Augustiniana e D. Augustini operibus compilata a Hieronymo Torrense*,” 1610, under the headings *De matrimonio*, *De cœlibatu*, &c., and any one may convince himself from these that in ancient, genuine Christianity marriage was only a concession, which besides this was supposed to have only the begetting of children as its end, that, on the other hand, perfect continence was the true virtue far to be preferred to this. To those, however, who do not wish to go back to the authorities themselves I recommend two works for the purpose of removing any kind of doubt as to

the tendency of Christianity we are speaking about: Carové, "*Ueber das Cölibatgesetz*," 1832, and Lind, "*De cœlibatu Christianorum per tria priora secula*," *Havniœ*, 1839. It is, however, by no means the views of these writers themselves to which I refer, for these are opposed to mine, but solely to their carefully collected accounts and quotations, which deserve full acceptance as quite trustworthy, just because both these writers are opponents of celibacy, the former a rationalistic Catholic, and the other a Protestant candidate in theology, who speaks exactly like one. In the first-named work we find, vol. i. p. 166, in that reference, the following result expressed: "In accordance with the Church view, as it may be read in canonical Church Fathers, in the Synodal and Papal instructions, and in innumerable writings of orthodox Catholics, perpetual chastity is called a divine, heavenly, angelic virtue, and the obtaining of the assistance of divine grace for this end is made dependent upon earnest prayer. We have already shown that this Augustinian doctrine is by Canisius and in the decrees of the Council of Trent expressed as an unchanging belief of the Church. That, however, it has been retained as a dogma till the present day is sufficiently established by the June number, 1831, of the magazine '*Der Katholik*.' It is said there, p. 263: 'In Catholicism the observance of a perpetual chastity, for the sake of God, appears as in itself the highest merit of man. The view that the observance of continual chastity as an end in itself sanctifies and exalts the man is, as every instructed Catholic is convinced, deeply rooted in Christianity, both as regards its spirit and its express precepts. The decrees of the Council of Trent have abolished all possible doubt on this point....' It must at any rate be confessed by every unprejudiced person, not only that the doctrine expressed by '*Der Katholik*' is really Catholic, but also that the proofs adduced may be quite irrefutable for a Catholic reason, because they are drawn so directly from the ecclesiastical view, taken by the Church, of life and its destiny." It is further said in the same work, p. 270: "Although both Paul calls the forbidding to marry a false doctrine, and the still Judaistic author of the Epistle to the Hebrews enjoins that marriage shall be held in honour by all, and the bed kept undefiled (Heb. xiii 4), yet the main tendency of these two sacred writers is not on that account to be mistaken. Virginity is for both the perfect state, marriage only a make-shift for the weak, and only as such to be held inviolable. The highest effort, on the other hand, was directed to complete, material putting off of self. The self must turn and refrain from all

that tends only to its own pleasure, and that only temporarily." Lastly, p. 288: "We agree with the Abbé Zaccaria, who asserts that celibacy (not the law of celibacy) is before everything to be deduced from the teaching of Christ and the Apostle Paul."

What is opposed to this specially Christian view is everywhere and always merely the Old Testament, with its παντα καλα λιαν. This appears with peculiar distinctness from that important third book of the Stromata of Clement, where, arguing against the encratistic heretics mentioned above, he constantly opposes to them only Judaism, with its optimistic history of creation, with which the world-denying tendency of the New Testament is certainly in contradiction. But the connection of the New Testament with the Old is at bottom only external, accidental, and forced; and the one point at which Christian doctrine can link itself on to the latter is only to be found, as has been said, in the story of the fall, which, moreover, stands quite isolated in the Old Testament, and is made no further use of. But, in accordance with the account in the Gospels, it is just the orthodox adherents of the Old Testament who bring about the crucifixion of the founder of Christianity, because they find his teaching in conflict with their own. In the said third book of the Stromata of Clement the antagonism between optimism with theism on the one hand, and pessimism with ascetic morality on the other, comes out with surprising distinctness. This book is directed against the Gnostics, who just taught pessimism and asceticism, that is, εγκρατεια (abstinence of every kind, but especially from all sexual satisfaction); on account of which Clement censures them vigorously. But, at the same time, it becomes apparent that even the spirit of the Old Testament stands in this antagonism with that of the New Testament. For, apart from the fall, which appears in the Old Testament like a *hors d'œuvre*, the spirit of the Old Testament is diametrically opposed to that of the New Testament — the former optimistic, the latter pessimistic. Clement himself brings this contradiction out prominently at the end of the eleventh chapter (προσαποτεινομενον τον Παυλον τῳ Κριστῃ κ.τ.λ.), although he will not allow that it is a real contradiction, but explains it as only apparent, — like a good Jew, as he is. In general it is interesting to see how with Clement the New and the Old Testament get mixed up together; and he strives to reconcile them, yet for the most part drives out the New Testament with the Old. Just at the beginning of the third chapter he objects to the Marcionites that they find fault with the creation, after the example of Plato and

Pythagoras; for Marcion teaches that nature is bad, made out of bad materials (φυσις κακη, εκ τε ὑλης κακης); therefore one ought not to people this world, but to abstain from marriage (μη βουλομενοι τον κοσμον συμπληρουν, απεχεσθαι γαμου). Now Clement, to whom in general the Old Testament is much more congenial and convincing than the New, takes this very much amiss. He sees in it their flagrant ingratitude to and enmity and rebellion against him who has made the world, the just demiurgus, whose work they themselves are, and yet despise the use of his creatures, in impious rebellion "forsaking the natural opinion" (αντιτασσομενοι τῳ ποιητῃ τῳ σφων, ... εγκρατεις τῃ προς τον πεποιηκοτα εχθρᾳ, μη βουλομενοι χρησθαι τοις ὑπ᾽ αυτου κτισθεισιν, ... ασεβει θεομαχιᾳ των κατα φυσιν εκσταντες λογισμωι). At the same time, in his holy zeal, he will not allow the Marcionites even the honour of originality, but, armed with his well-known erudition, he brings it against them, and supports his case with the most beautiful quotations, that even the ancient philosophers, that Heraclitus and Empedocles, Pythagoras and Plato, Orpheus and Pindar, Herodotus and Euripides, and also the Sibyls, lamented deeply the wretched nature of the world, thus taught pessimism. Now in this learned enthusiasm he does not observe that in this way he is just giving the Marcionites water for their mill, for he shows that

"All the wisest of all the ages"

have taught and sung what they do, but confidently and boldly he quotes the most decided and energetic utterances of the ancients in this sense. Certainly they cannot lead him astray. Wise men may mourn the sadness of existence, poets may pour out the most affecting lamentations about it, nature and experience may cry out as loudly as they will against optimism, — all this does not touch our Church Father: he holds his Jewish revelation in his hand, and remains confident. The demiurgus made the world. From this it is *a priori* certain that it is excellent, and it may look as it likes. The same thing then takes place with regard to the second point, the εγκρατεια, through which, according to his view, the Marcionites show their ingratitude towards the demiurgus (αχαρισειν τῳ δημιουργῳ) and the perversity with which they put from them all his gifts (δἰ αντιταξιν προς τον δημιουργον, την χρησιν των κοσμικων παραιτουμενοι). Here now the tragic poets have preceded the Encratites (to the prejudice of their originality) and have said the same things. For since they also lament the infinite misery of existence, they have added that it is better to bring no children into such a

world; which he now again supports with the most beautiful passages, and, at the same time, accuses the Pythagoreans of having renounced sexual pleasure on this ground. But all this touches him not; he sticks to his principle that all these sin against the demiurgus, in that they teach that one ought not to marry, ought not to beget children, ought not to bring new miserable beings into the world, ought not to provide new food for death (δἰ εγκρατειας ασεβουσι εις τε την κτισιν και τον ἁγιον δημιουργον, τον παντοκρατορα μονον θεον, και διδασκουσι, μη δειν παραδεχεσθαι γαμον και παιδοποιϊαν, μηδε αντεισαγειν τῳ κοσμῳ δυστυχησοντας ἑτερους, μηδε επιχορηγειν θανατῳ τροφην — c. 6). Since the learned Church Father thus denounces εγκρατεια, he seems to have had no presentiment that just after his time the celibacy of the Christian priesthood would be more and more introduced, and finally, in the eleventh century, raised to the position of a law, because it is in keeping with the spirit of the New Testament. It is just this spirit which the Gnostics have grasped more profoundly and understood better than our Church Father, who is more Jew than Christian. The conception of the Gnostics comes out very clearly at the beginning of the ninth chapter, where the following passage is quoted from the Gospel of the Egyptians: Αυτος ειπεν ὁ Σωτηρ, “ηλθον καταλυσαι τα εργα της θηλειας;” θηλειας μεν, της επιθυμιας; εργα δε, γενεσιν και φθοραν (*Ajunt enim dixisse Servatorem: veni ad dissolvendum opera feminæ; feminæ quidem, cupiditatis; opera autem, generationem et interitum*); but quite specially at the end of the thirteenth and the beginning of the fourteenth chapter. The Church certainly was obliged to consider how to set a religion upon its legs that could also walk and stand in the world as it is, and among men; therefore it declared these persons to be heretics. At the conclusion of the seventh chapter our Church Father opposes Indian asceticism, as bad, to Christian Judaism; whereby the fundamental difference of the spirit of the two religions is clearly brought out. In Judaism and Christianity everything runs back to obedience or disobedience to the command of God: ὑπακοη και παρακοη; as befits us creatures, ἡμιν, τοις πεπλασμενοις ὑπο της του Παντοκρατορος βουλησεως (*nobis, qui Omnipotentis voluntate effecti sumus*), chap. 14. Then comes, as a second duty, λατρευειν θεῳ ζωντι, to serve God, extol His works, and overflow with thankfulness. Certainly the matter has a very different aspect in Brahmanism and Buddhism, for in the latter all improvement and conversion, and the only deliverance we can hope for from this world of suffering, this Sansara, proceeds from the

knowledge of the four fundamental truths: (1) *dolor*; (2) *doloris ortus*; (3) *doloris interitus*; (4) *octopartita via ad doloris sedationem* (*Dammapadam*, ed. Fausböll, p. 35 *et* 347). The explanation of these four truths will be found in Bournouf, "*Introduct. à l'hist. du Buddhisme*," p. 629, and in all expositions of Buddhism.

In truth, Judaism, with its παντα καλα λιαν, is not related to Christianity as regards its spirit and ethical tendency, but Brahmanism and Buddhism are. But the spirit and ethical tendency are what is essential in a religion, not the myths in which these are clothed. I therefore cannot give up the belief that the doctrines of Christianity can in some way be derived from these primitive religions. I have pointed out some traces of this in the second volume of the Parerga, § 179 (second edition, § 180). I have to add to these that Epiphanias (*Hæretic*. xviii.) relates that the first Jewish Christians of Jerusalem, who called themselves Nazarenes, refrained from all animal food. On account of this origin (or, at least, this agreement) Christianity belongs to the ancient, true and sublime faith of mankind, which is opposed to the false, shallow, and injurious optimism which exhibits itself in Greek paganism, Judaism, and Islamism. The Zend religion holds to a certain extent the mean, because it has opposed to Ormuzd a pessimistic counterpoise in Ahriman. From this Zend religion the Jewish religion proceeded, as J.G. Rhode has thoroughly proved in his book, "*Die heilige Sage des Zendvolks*;" from Ormuzd has come Jehovah, and from Ahriman, Satan, who, however, plays only a very subordinate rôle in Judaism, indeed almost entirely disappears, whereby then optimism gains the upper hand, and there only remains the myth of the fall as a pessimistic element, which certainly (as the fable of Meschia and Meschiane) is derived from the Zend-Avesta. Yet even this falls into oblivion, till it is again taken up by Christianity along with Satan. Ormuzd himself, however, is derived from Brahmanism, although from a lower region of it; he is no other than Indra, that subordinate god of the firmament and the atmosphere, who is represented as frequently in rivalry with men. This has been very clearly shown by J.J. Schmidt in his work on the relation of the Gnostic-theosophic doctrines to the religions of the East. This Indra-Ormuzd-Jehovah had afterwards to pass over into Christianity, because this religion arose in Judæa. But on account of the cosmopolitan character of Christianity he laid aside his own name to be denoted in the language of each converted nation by the appellation of the superhuman beings he supplanted, as, Δεος, *Deus*,

which comes from the Sanscrit *Deva* (from which also devil comes), or among the Gothico-Germanic peoples by the word God, *Gott*, which comes from *Odin*, *Wodan*, *Guodan*, *Godan*. In the same way he assumed in Islamism, which also sprang from Judaism, the name of Allah, which also existed earlier in Arabia. Analogous to this, the gods of the Greek Olympus, when in prehistoric times they were transplanted to Italy, also assumed the names of the previously reigning gods: hence among the Romans Zeus is called Jupiter, Hera Juno, Hermes Mercury, &c. In China the first difficulty of the missionaries arose from the fact that the Chinese language has no appellation of the kind and also no word for creating; for the three religions of China know no gods either in the plural or in the singular.[52]

However the rest may be, that παντα καλα λιαν of the Old Testament is really foreign to true Christianity; for in the New Testament the world is always spoken of as something to which one does not belong, which one does not love, nay, whose lord is the devil.[53] This agrees with the ascetic spirit of the denial of one's self and the overcoming of the world which, just like the boundless love of one's neighbour, even of one's enemy, is the fundamental characteristic which Christianity has in common with Brahmanism and Buddhism, and which proves their relationship. There is nothing in which one has to distinguish the kernel so carefully from the shell as in Christianity. Just because I prize this kernel highly I sometimes treat the shell with little ceremony; it is, however, thicker than is generally supposed. Protestantism, since it has eliminated asceticism and its central point, the meritoriousness of celibacy, has already given up the inmost kernel of Christianity, and so far is to be regarded as a falling away from it. This has become apparent in our own day by the gradual transition of Protestantism into shallow rationalism, this modern Pelagianism, which ultimately degenerates into the doctrine of a loving father, who has made the world, in order that things may go on very pleasantly in it (in which case, then, he must certainly have failed), and who, if one only conforms to his will in certain respects, will also afterwards provide a still more beautiful world (with regard to which it is only a pity that it has such a fatal entrance). That may be a good religion for comfortable, married, and enlightened Protestant pastors; but it is no Christianity. Christianity is the doctrine of the deep guilt of the human race through its existence alone, and the longing of the heart for deliverance from it, which, however, can only be attained by the greatest sacrifices and by the denial of one's own self,

thus by an entire reversal of human nature. Luther may have been perfectly right from the practical point of view, *i.e.*, with reference to the Church scandal of his time, which he wished to remove, but not so from the theoretical point of view. The more sublime a doctrine is, the more it is exposed to abuse at the hands of human nature, which, on the whole, is of a low and evil disposition: hence the abuses of Catholicism are so much more numerous and so much greater than those of Protestantism. Thus, for example, monasticism, that methodical denial of the will practised in common for the sake of mutual encouragement, is an institution of a sublime description, which, however, for this very reason is for the most part untrue to its spirit. The shocking abuses of the Church excited in the honest mind of Luther a lofty indignation. But in consequence of this he was led to desire to limit as much as possible the claims of Christianity itself, and for this end he first confined it to the words of the Bible; but then, in his well-meant zeal, he went too far, for he attacked the very heart of Christianity in the ascetic principle. For after the withdrawal of the ascetic principle, the optimistic principle soon necessarily took its place. But in religions, as in philosophy, optimism is a fundamental error which obstructs the path of all truth. From all this it seems to me that Catholicism is a shamefully abused, but Protestantism a degenerate Christianity; thus, that Christianity in general has met the fate which befalls all that is noble, sublime, and great whenever it has to dwell among men.

However, even in the very lap of Protestantism, the essentially ascetic and encratistic spirit of Christianity has made way for itself; and in this case it has appeared in a phenomenon which perhaps has never before been equalled in magnitude and definiteness, the highly remarkable sect of the Shakers, in North America, founded by an Englishwoman, Anne Lee, in 1774. The adherents of this sect have already increased to 6000, who are divided into fifteen communities, and inhabit a number of villages in the states of New York and Kentucky, especially in the district of New Lebanon, near Nassau village. The fundamental characteristic of their religious rule of life is celibacy and entire abstention from all sexual satisfaction. It is unanimously admitted, even by the English and Americans who visit them, and who laugh and jeer at them in every other respect, that this rule is strictly and with perfect honesty observed; although brothers and sisters sometimes even occupy the same house, eat at the same table, nay, *dance* together in the religious services in church. For whoever has made

that hardest of all sacrifices may *dance* before the Lord; he is a victor, he has overcome. Their singing in church consists in general of cheerful, and partly even of merry, songs. The church-dance, also, which follows the sermon is accompanied by the singing of the rest. It is a lively dance, performed in measured time, and concludes with a galop, which is carried on till the dancers are exhausted. Between each dance one of their teachers cries aloud, “Think, that ye rejoice before the Lord for having slain your flesh; for this is here the only use we make of our refractory limbs.” To celibacy most of the other conditions link themselves on of themselves. There are no families, and therefore there is no private property, but community of goods. All are clothed alike, in Quaker fashion, and with great neatness. They are industrious and diligent: idleness is not endured. They have also the enviable rule that they are to avoid all unnecessary noise, such as shouting, door-slamming, whip-cracking, loud knocking, &c. Their rule of life has been thus expressed by one of them: “Lead a life of innocence and purity, love your neighbours as yourself, live at peace with all men, and refrain from war, blood-shed, and all violence against others, as well as from all striving after worldly honour and distinction. Give to each his own, and follow after holiness, without which no man can see the Lord. Do good to all so far as your opportunity and your power extends.” They persuade no one to join them, but test those who present themselves by a novitiate of several years. Moreover, every one is free to leave them; very rarely is any one expelled for misconduct. Adopted children are carefully educated, and only when they are grown up do they voluntarily join the sect. It is said that in the controversies of their ministers with Anglican clergy the latter generally come off the worse, for the arguments consist of passages from the New Testament. Fuller accounts of them will be found particularly in Maxwell’s “Run through the United States,” 1841; also in Benedict’s “History of all Religions,” 1830; also in the *Times*, November 4, 1837, and in the German magazine *Columbus*, May number, 1831. A German sect in America, very similar to them, who also live in strict celibacy and continence, are the Rappists. An account of them is given in F. Loher’s “*Geschichte und Zustande der Deutschen in Amerika*,” 1853.
In Russia also the Raskolniks are a similar sect. The Gichtelians live also in strict chastity. But among the ancient Jews we already find a prototype of all these sects, the Essenes, of whom even Pliny gives an account (*Hist. Nat.*, v. 15), and who resembled the Shakers very much, not only in

celibacy, but also in other respects; for example, in dancing during divine service, which leads to the opinion that the founder of the Shakers took the Essenes as a pattern. In the presence of such facts as these how does Luther's assertion look: "*Ubi natura, quemadmodum a Deo nobis insita est, fertur ac rapitur*, fieri nullo modo potest, *ut extra matrimonium caste vivatur*"? (*Catech. maj.*)

Although Christianity, in essential respects, taught only what all Asia knew long before, and even better, yet for Europe it was a new and great revelation, in consequence of which the spiritual tendency of the European nations was therefore entirely transformed. For it disclosed to them the metaphysical significance of existence, and therefore taught them to look away from the narrow, paltry, ephemeral life of earth, and to regard it no longer as an end in itself, but as a condition of suffering, guilt, trial, conflict, and purification, out of which, by means of moral achievements, difficult renunciation, and denial of oneself, one may rise to a better existence, which is inconceivable by us. It taught the great truth of the assertion and denial of the will to live in the clothing of allegory by saying that through Adam's fall the curse has come upon all, sin has come into the world, and guilt is inherited by all; but that, on the other hand, through the sacrificial death of Jesus all are reconciled, the world saved, guilt abolished, and justice satisfied. In order, however, to understand the truth itself that is contained in this myth one must not regard men simply in time, as beings independent of each other, but must comprehend the (Platonic) Idea of man, which is related to the series of men, as eternity in itself is related to eternity drawn out as time; hence the eternal Idea *man* extended in time to the series of men through the connecting bond of generation appears again in time as a whole. If now we keep the Idea of man in view, we see that Adam's fall represents the finite, animal, sinful nature of man, in respect of which he is a finite being, exposed to sin, suffering, and death. On the other hand, the life, teaching, and death of Jesus Christ represent the eternal, supernatural side, the freedom, the salvation of man. Now every man, as such and *potentiâ*, is both Adam and Jesus, according as he comprehends himself, and his will thereupon determines him; in consequence of which he is then condemned and given over to death, or saved and attains to eternal life. Now these truths, both in their allegorical and in their real acceptation, were completely new as far as Greeks and Romans were concerned, who were still entirely absorbed in life, and did not seriously look beyond it. Let

whoever doubts this see how Cicero (*Pro Cluentio*, c. 61) and Sallust (*Catil.*, c. 47) speak of the state after death. The ancients, although far advanced in almost everything else, remained children with regard to the chief concern, and were surpassed in this even by the Druids, who at least taught metempsychosis. That one or two philosophers, like Pythagoras and Plato, thought otherwise alters nothing as regards the whole.

That great fundamental truth, then, which is contained in Christianity, as in Brahmanism and Buddhism, the need of deliverance from an existence which is given up to suffering and death, and the attainableness of this by the denial of the will, thus by a decided opposition to nature, is beyond all comparison the most important truth there can be; but, at the same time, it is entirely opposed to the natural tendency of the human race, and in its true grounds it is difficult to comprehend; as indeed all that can only be thought generally and in the abstract is inaccessible to the great majority of men. Therefore for these men there was everywhere required, in order to bring that great truth within the sphere of its practical application, *a mythical vehicle* for it, as it were a receptacle, without which it would be lost and dissipated. The truth had therefore everywhere to borrow the garb of the fable, and also constantly to endeavour to connect itself with what in each case was historically given, already familiar, and already revered. What *sensu proprio* remained inaccessible to the great mass of mankind of all ages and lands, with their low tone of mind, their intellectual stupidity and general brutality, had, for practical purposes, to be brought home to them *sensu allegorico*, in order to become their guiding star. So, then, the religions mentioned above are to be regarded as the sacred vessels in which the great truth, known and expressed for several thousand years, indeed perhaps since the beginning of the human race, which yet in itself, for the great mass of mankind always remains a mystery, is, according to the measure of their powers, made accessible to them, preserved and transmitted through the centuries. Yet, because all that does not through and through consist of the imperishable material of pure truth is subject to destruction, whenever this fate befalls such a vessel, through contact with a heterogeneous age, its sacred content must in some way be saved and preserved for mankind by another. But it is the task of philosophy, since it is one with pure truth, to present that content pure and unmixed, thus merely in abstract conceptions, and consequently without that vehicle, for those who are capable of thinking, who are always an exceedingly small number.

It is therefore related to religions as a straight line to several curves running near it: for it expresses *sensu proprio*, thus reaches directly, what they show in veiled forms and reach by circuitous routes.

If now, in order to illustrate what has just been said by an example, and also to follow a philosophical fashion of my time, I should wish perhaps to attempt to solve the profoundest mystery of Christianity, that of the Trinity, in the fundamental conception of my philosophy, this could be done, with the licence permitted in such interpretations, in the following manner. The Holy Ghost is the distinct denial of the will to live: the man in whom this exhibits itself *in concreto* is the Son; He is identical with the will which asserts life, and thereby produces the phenomenon of this perceptible world, *i.e.*, with the Father, because the assertion and denial are opposite acts of the same will whose capability for both is the only true freedom. However, this is to be regarded as a mere *lusus ingenii*.

Before I close this chapter I wish to adduce a few proofs in support of what in § 68 of the first volume I denoted by the expression Δευτυρος πλους, the bringing about of the denial of the will by one's own deeply felt suffering, thus not merely by the appropriation of the suffering of others, and the knowledge of the vanity and wretchedness of our existence introduced by this. We can arrive at a comprehension of what goes on in the heart of a man, in the case of an elevation of this kind and the accompanying purifying process, by considering what every emotional man experiences on beholding a tragedy, which is of kindred nature to this. In the third and fourth acts perhaps such a man is distressed and disturbed by the ever more clouded and threatened happiness of the hero; but when, in the fifth act, this happiness is entirely wrecked and shattered, he experiences a certain elevation of the soul, which affords him an infinitely higher kind of pleasure than the sight of the happiness of the hero, however great it might be, could ever have given. Now this is the same thing, in the weak water-colours of sympathy which is able to raise a well-known illusion, as that which takes place with the energy of reality in the feeling of our own fate when it is heavy misfortune that drives the man at last into the haven of entire resignation. Upon this occurrence depend all those conversions which completely transform men such as are described in the text. I may give here in a few words the story of the conversion of the Abbé Rancé, as it is strikingly similar to that of Raymond Lully, which is told in the text, and besides this is memorable on account of its result. His youth

was devoted to enjoyment and pleasure; finally, he lived in a relation of passion with a Madame de Montbazon. One evening, when he visited her, he found her room empty, in disorder and darkness. He struck something with his foot; it was her head, which had been severed from the trunk, because after her sudden death her corpse could not otherwise be got into the lead coffin that stood beside it. After overcoming an immense sorrow, Rancé now became, in 1663, the reformer of the order of the Trappists, which at that time had entirely relaxed the strictness of its rules. He joined this order, and through him it was led back to that terrible degree of renunciation which is still maintained at the present day at La Trappe, and, as the methodically carried out denial of the will, aided by the severest renunciation and an incredibly hard and painful manner of life, fills the visitor with sacred awe, after he has been touched at his reception by the humility of these genuine monks, who, emaciated by fasting, by cold, by night watches, prayers and penances, kneel before him, the worldling and the sinner, to implore his blessing. Of all orders of monks, this one alone has maintained itself in perfection in France, through all changes; which is to be attributed to the profound earnestness which in it is unmistakable, and excludes all secondary ends. It has remained untouched even by the decline of religion, because its root lies deeper in human nature than any positive system of belief.

I have mentioned in the text that this great and rapid change of the inmost being of man which we are here considering, and which has hitherto been entirely neglected by philosophers, appears most frequently when, with full consciousness, he stands in the presence of a violent and certain death, thus in the case of executions. But, in order to bring this process much more distinctly before our eyes, I regard it as by no means unbecoming to the dignity of philosophy to quote what has been said by some criminals before their execution, even at the risk of incurring the sneer that I encourage gallows' sermons. I certainly rather believe that the gallows is a place of quite peculiar revelations, and a watch-tower from which the man who even then retains his presence of mind obtains a wider, clearer outlook into eternity than most philosophers over the paragraphs of their rational psychology and theology. The following speech on the gallows was made on the 15th April, 1837, at Gloucester, by a man called Bartlett, who had murdered his mother-in-law: "Englishmen and fellow countrymen, — I have a few words to say to you, and they shall be but very

few. Yet let me entreat you, one and all, that these few words that I shall utter may strike deep into your hearts. Bear them in your mind, not only now while you are witnessing this sad scene, but take them to your homes, take them, and repeat them to your children and friends. I implore you as a dying man — one for whom the instrument of death is even now prepared — and these words are that you may loose yourselves from the love of this dying world and its vain pleasures. Think less of it and more of your God. Do this: repent, repent, for be assured that without deep and true repentance, without turning to your heavenly Father, you will never attain, nor can hold the slightest hope of ever reaching those bowers of bliss to which I trust I am now fast advancing" (*Times*, 18th April 1837).

Still more remarkable are the last words of the well-known murderer, Greenacre, who was executed in London on the 1st of May 1837. The English newspaper the *Post* gives the following account, which is also reprinted in *Galignani's Messenger* of the 6th of May 1837: "On the morning of his execution a gentleman advised him to put his trust in God, and pray for forgiveness through the mediation of Jesus Christ. Greenacre replied that forgiveness through the mediation of Christ was a matter of opinion; for his part, he believed that in the sight of the highest Being, a Mohammedan was as good as a Christian and had just as much claim to salvation. Since his imprisonment he had had his attention directed to theological subjects, and he had become convinced that the gallows is a passport to heaven." The indifference displayed here towards positive religions is just what gives this utterance greater weight, for it shows that it is no fanatical delusion, but individual immediate knowledge that lies at its foundation. The following incident may also be mentioned which is given by *Galignani's Messenger* of the 15th August 1837, from the *Limerick Chronicle*: "Last Monday Maria Cooney was executed for the revolting murder of Mrs. Anderson. So deeply was this wretched woman impressed with the greatness of her crime that she kissed the rope which was put round her neck, while she humbly implored the mercy of God." Lastly this: the *Times*, of the 29th April 1845 gives several letters which Hocker, who was condemned for the murder of Delarue, wrote the day before his execution. In one of these he says: "I am persuaded that unless the natural heart be broken, and renewed by divine mercy, however noble and amiable it may be deemed by the world, it can never think of eternity without inwardly shuddering." These are the outlooks into eternity referred to above which

are obtained from that watch-tower; and I have had the less hesitation in giving them here since Shakspeare also says —

"Out of these convertites
There is much matter to be heard and learned."
— *As You Like it*, last scene.

Strauss, in his "Life of Jesus," has proved that Christianity also ascribes to suffering as such the purifying and sanctifying power here set forth (*Leben Jesu*, vol. i. ch. 6, §§ 72 and 74). He says that the beatitudes in the Sermon on the Mount have a different sense in Luke (vi. 21) from that which they have in Matt. (v. 3), for only the latter adds τῳ πνευματι to μακαριοι οἱ πτωχοι, and την δικαιοσυνην to πεινωντες. Thus by him alone are the simple-minded, the humble, &c., meant, while by Luke are meant the literally poor; so that here the contrast is that between present suffering and future happiness. With the Ebionites it is a capital principle that whoever takes his portion in this age gets nothing in the future, and conversely. Accordingly in Luke the blessings are followed by as many ουαι, woes, which are addressed to the rich, οἱ πλουσιοι, the full, οἱ εμπεπλησμενοι, and to them that laugh, οἱ γελωντες, in the Ebionite spirit. In the same spirit, he says, p. 604, is the parable (Luke xvi. 19) of the rich man and Lazarus given, which nowhere mentions any fault of the former or any merit of the latter, and takes as the standard of the future recompense, not the good done or the wickedness practised, but the evil suffered here and the good things enjoyed, in the Ebionite spirit. "A like estimation of outward poverty," Strauss goes on, "is also attributed to Jesus by the other synoptists (Matt. xix. 16; Mark x. 17; Luke xviii. 18), in the story of the rich young man and the saying about the camel and the eye of a needle."

If we go to the bottom of the matter we will recognise that even in the most famous passages of the Sermon on the Mount there is contained an indirect injunction to voluntary poverty, and thereby to the denial of the will to live. For the precept (Matt. v. 40 *seq.*) to consent unconditionally to all demands made upon us, to give our cloak also to him who will take away our coat, &c., similarly (Matt. vi. 25-34) the precept to cast aside all care for the future, even for the morrow, and so to live simply in the present, are rules of life the observance of which inevitably leads to absolute poverty, and which therefore just say in an indirect manner what Buddha directly commands his disciples and has confirmed by his own example: throw everything away and become bhikkhu, *i.e.*, beggars. This appears still more

decidedly in the passage Matt. x. 9-15, where all possessions, even shoes and a staff, are forbidden to the Apostles, and they are directed to beg. These commands afterwards became the foundation of the mendicant order of St. Francis (*Bonaventuræ vita S. Francisci*, c. 3). Hence, then, I say that the spirit of Christian ethics is identical with that of Brahmanism and Buddhism. In conformity with the whole view expounded here Meister Eckhard also says (Works, vol. i. p. 492): "The swiftest animal that bears thee to perfection is suffering."

Chapter XLIX. The Way Of Salvation.

There is only one inborn error, and that is, that we exist in order to be happy. It is inborn in us because it is one with our existence itself, and our whole being is only a paraphrase of it, nay, our body is its monogram. We are nothing more than will to live and the successive satisfaction of all our volitions is what we think in the conception of happiness.

As long as we persist in this inborn error, indeed even become rigidly fixed in it through optimistic dogmas, the world appears to us full of contradictions. For at every step, in great things as in small, we must experience that the world and life are by no means arranged with a view to containing a happy existence. While now by this the thoughtless man only finds himself tormented in reality, in the case of him who thinks there is added to his real pain the theoretical perplexity why a world and a life which exist in order that one may be happy in them answer their end so badly. First of all it finds expression in pious ejaculations, such as, "Ah! why are the tears on earth so many?" &c. &c. But in their train come disquieting doubts about the assumptions of those preconceived optimistic dogmas. One may try if one will to throw the blame of one's individual unhappiness now upon the circumstances, now upon other men, now upon one's own bad luck, or even upon one's own awkwardness, and may know well how all these have worked together to produce it; but this in no way alters the result that one has missed the real end of life, which consists indeed in being happy. The consideration of this is, then, often very depressing, especially if life is already on the wane; hence the countenances of almost all elderly persons wear the expression of that which in English is called disappointment. Besides this, however, hitherto every day of our life has taught us that joys and pleasures, even if attained, are in themselves delusive, do not perform what they promise, do not satisfy the heart, and finally their possession is at least embittered by the disagreeables that accompany them or spring from them; while, on the contrary, the pains and sorrows prove themselves very real, and often exceed all expectation. Thus certainly everything in life is calculated to recall us from that original error, and to convince us that the end of our existence is not to be happy. Indeed, if we regard it more closely and without prejudice, life rather presents itself as specially intended to be such that we shall *not* feel ourselves happy in it,

for through its whole nature it bears the character of something for which we have no taste, which must be endured by us, and from which we have to return as from an error that our heart may be cured of the passionate desire of enjoyment, nay, of life, and turned away from the world. In this sense, it would be more correct to place the end of life in our woe than in our welfare. For the considerations at the conclusion of the preceding chapter have shown that the more one suffers the sooner one attains to the true end of life, and that the more happily one lives the longer this is delayed. The conclusion of the last letter of Seneca corresponds with this: *bonum tunc habebis tuum, quum intelliges infelicissimos esse felices*; which certainly seems to show the influence of Christianity. The peculiar effect of the tragic drama also ultimately depends upon the fact that it shakes that inborn error by vividly presenting in a great and striking example the vanity of human effort and the nothingness of this whole existence, and thus discloses the profound significance of life; hence it is recognised as the sublimest form of poetry. Whoever now has returned by one or other path from that error which dwells in us *a priori*, that πρωτου ψευδος of our existence, will soon see all in another light, and will now find the world in harmony with his insight, although not with his wishes. Misfortunes of every kind and magnitude, although they pain him, will no longer surprise him, for he has come to see that it is just pain and trouble that tend towards the true end of life, the turning away of the will from it. This will give him indeed a wonderful composedness in all that may happen, similar to that with which a sick person who undergoes a long and painful cure bears the pain of it as a sign of its efficacy. In the whole of human existence suffering expresses itself clearly enough as its true destiny. Life is deeply sunk in suffering, and cannot escape from it; our entrance into it takes place amid tears, its course is at bottom always tragic, and its end still more so. There is an unmistakable appearance of intention in this. As a rule man's destiny passes through his mind in a striking manner, at the very summit of his desires and efforts, and thus his life receives a tragic tendency by virtue of which it is fitted to free him from the passionate desire of which every individual existence is an example, and bring him into such a condition that he parts with life without retaining a single desire for it and its pleasures. Suffering is, in fact, the purifying process through which alone, in most cases, the man is sanctified, *i.e.*, is led back from the path of error of the will to live. In accordance with this, the salutary nature of the cross and of suffering is

so often explained in Christian books of edification, and in general the cross, an instrument of suffering, not of doing, is very suitably the symbol of the Christian religion. Nay, even the Preacher, who is still Jewish, but so very philosophical, rightly says: "Sorrow is better than laughter: for by the sadness of the countenance the heart is made better" (Eccles. vii. 3). Under the name of the δεντρος πλους I have presented suffering as to a certain extent a substitute for virtue and holiness; but here I must make the bold assertion that, taking everything into consideration, we have more to hope for our salvation and deliverance from what we suffer than from what we do. Precisely in this spirit Lamartine very beautifully says in his "*Hymne à la douleur*," apostrophising pain: —

"*Tu me traites sans doute en favori des cieux,*
Car tu n'épargnes pas les larmes à mes yeux.
Eh bien! je les reçois comme tu les envoies,
Tes maux seront mes biens, et tes soupirs mes joies.
Je sens qu'il est en toi, sans avoir combattu,
Une vertu divine au lieu de ma vertu,
Que tu n'es pas la mort l'âme, mais sa vie,
Que ton bras, en frappant, guérit et vivifie."

If, then, suffering itself has such a sanctifying power, this will belong in an even higher degree to death, which is more feared than any suffering. Answering to this, a certain awe, kindred to that which great suffering occasions us, is felt in the presence of every dead person, indeed every case of death presents itself to a certain extent as a kind of apotheosis or canonisation; therefore we cannot look upon the dead body of even the most insignificant man without awe, and indeed, extraordinary as the remark may sound in this place, in the presence of every corpse the watch goes under arms. Dying is certainly to be regarded as the real aim of life: in the moment of death all that is decided for which the whole course of life was only the preparation and introduction. Death is the result, the *Résumé* of life, or the added up sum which expresses at once the instruction which life gave in detail, and bit by bit; this, that the whole striving whose manifestation is life was a vain, idle, and self-contradictory effort, to have returned from which is a deliverance. As the whole, slow vegetation of the plant is related to the fruit, which now at a stroke achieves a hundredfold what the plant achieved gradually and bit by bit, so life, with its obstacles, deluded hopes, frustrated plans, and constant suffering, is related to death,

which at one stroke destroys all, all that the man has willed, and so crowns the instruction which life gave him. The completed course of life upon which the dying man looks back has an effect upon the whole will that objectifies itself in this perishing individuality, analogous to that which a motive exercises upon the conduct of the man. It gives it a new direction, which accordingly is the moral and essential result of the life. Just because a sudden death makes this retrospect impossible, the Church regards such a death as a misfortune, and prays that it should be averted. Since this retrospect, like the distinct foreknowledge of death, as conditioned by the reason, is possible only in man, not in the brute, and accordingly man alone really drinks the cup of death, humanity is the only material in which the will can deny itself and entirely turn away from life. To the will that does not deny itself every birth imparts a new and different intellect, — till it has learned the true nature of life, and in consequence of this wills it no more.

In the natural course, in age the decay of the body coincides with that of the will. The desire for pleasures soon vanishes with the capacity to enjoy them. The occasion of the most vehement willing, the focus of the will, the sexual impulse, is first extinguished, whereby the man is placed in a position which resembles the state of innocence which existed before the development of the genital system. The illusions, which set up chimeras as exceedingly desirable benefits, vanish, and the knowledge of the vanity of all earthly blessings takes their place. Selfishness is repressed by the love of one's children, by means of which the man already begins to live more in the ego of others than in his own, which now will soon be no more. This course of life is at least the desirable one; it is the euthanasia of the will. In hope of this the Brahman is ordered, after he has passed the best years of his life, to forsake possessions and family, and lead the life of a hermit (*Menu*, B. 6), But if, conversely, the desire outlives the capacity for enjoyment, and we now regret particular pleasures in life which we miss, instead of seeing the emptiness and vanity of all; and if then gold, the abstract representative of the objects of desire for which the sense is dead, takes the place of all these objects themselves, and now excites the same vehement passions which were formerly more pardonably awakened by the objects of actual pleasure, and thus now with deadened senses a lifeless but indestructible object is desired with equally indestructible eagerness; or, also, if, in the same way, existence in the opinion of others takes the place of existence and action in the real world, and now kindles the same

passions; — then the will has become sublimated and etherealised into avarice or ambition; but has thereby thrown itself into the last fortress, in which it can only now be besieged by death. The end of existence has been missed.

All these considerations afford us a fuller explanation of that purification, conversion of the will and deliverance, denoted in the preceding chapter by the expression δευτερος πλους which is brought about by the suffering of life, and without doubt is the most frequent. For it is the way of sinners such as we all are. The other way, which leads to the same goal, by means of mere knowledge and the consequent appropriation of the suffering of a whole world, is the narrow path of the elect, the saints, and therefore to be regarded as a rare exception. Therefore without that first way for most of us there would be no salvation to hope for. However, we struggle against entering upon it, and strive rather to procure for ourselves a safe and agreeable existence, whereby we chain our will ever more firmly to life. The conduct of the ascetics is the opposite of this. They make their life intentionally as poor, hard, and empty of pleasure as possible, because they have their true and ultimate welfare in view. But fate and the course of things care for us better than we ourselves, for they frustrate on all sides our arrangements for an utopian life, the folly of which is evident enough from its brevity, uncertainty, and emptiness, and its conclusion by bitter death; they strew thorns upon thorns in our path, and meet us everywhere with healing sorrow, the panacea of our misery. What really gives its wonderful and ambiguous character to our life is this, that two diametrically opposite aims constantly cross each other in it; that of the individual will directed to chimerical happiness in an ephemeral, dream-like, and delusive existence, in which, with reference to the past, happiness and unhappiness are a matter of indifference, and the present is every moment becoming the past; and that of fate visibly enough directed to the destruction of our happiness, and thereby to the mortification of our will and the abolition of the illusion that holds us chained in the bonds of this world.

The prevalent and peculiarly Protestant view that the end of life lies solely and immediately in the moral virtues, thus in the practice of justice and benevolence, betrays its insufficiency even in the fact that so miserably little real and pure morality is found among men. I am not speaking at all of lofty virtue, nobleness, magnanimity, and self-sacrifice, which one hardly finds anywhere but in plays and novels, but only of those virtues which are

the duty of every one. Let whoever is old think of all those with whom he has had to do; how many persons will he have met who were merely really and truly *honest*? Were not by far the greater number, in spite of their shameless indignation at the slightest suspicion of dishonesty or even untruthfulness, in plain words, the precise opposite? Were not abject selfishness, boundless avarice, well-concealed knavery, and also poisonous envy and fiendish delight in the misfortunes of others so universally prevalent that the slightest exception was met with surprise? And benevolence, how very rarely it extends beyond a gift of what is so superfluous that one never misses it. And is the whole end of existence to lie in such exceedingly rare and weak traces of morality? If we place it, on the contrary, in the entire reversal of this nature of ours (which bears the evil fruits just mentioned) brought about by suffering, the matter gains an appearance of probability and is brought into agreement with what actually lies before us. Life presents itself then as a purifying process, of which the purifying lye is pain. If the process is carried out, it leaves behind it the previous immorality and wickedness as refuse, and there appears what the Veda says: "*Finditur nodus cordis, dissolvuntur omnes dubitationes, ejusque opera evanescunt.*" As agreeing with this view the fifteenth sermon of Meister Eckhard will be found very well worth reading.

Chapter L. Epiphilosophy.

At the conclusion of my exposition a few reflections concerning my philosophy itself may find their place. My philosophy does not pretend to explain the existence of the world in its ultimate grounds: it rather sticks to the facts of external and internal experience as they are accessible to every one, and shows the true and deepest connection of them without really going beyond them to any extra-mundane things and their relations to the world. It therefore arrives at no conclusions as to what lies beyond all possible experience, but affords merely an exposition of what is given in the external world and in self-consciousness, thus contents itself with comprehending the nature of the world in its inner connection with itself. It is consequently *immanent*, in the Kantian sense of the word. But just on this account it leaves many questions untouched; for example, why what is proved as a fact is as it is and not otherwise, &c. All such questions, however, or rather the answers to them, are really transcendent, *i.e.*, they cannot be thought by the forms and functions of our intellect, do not enter into these; it is therefore related to them as our sensibility is related to the possible properties of bodies for which we have no senses. After all my explanations one may still ask, for example, whence has sprung this will that is free to assert itself, the manifestation of which is the world, or to deny itself, the manifestation of which we do not know. What is the fatality lying beyond all experience which has placed it in the very doubtful dilemma of either appearing as a world in which suffering and death reign, or else denying its very being? — or again, what can have prevailed upon it to forsake the infinitely preferable peace of blessed nothingness? An individual will, one may add, can only turn to its own destruction through error in the choice, thus through the fault of knowledge; but the will in itself, before all manifestation, consequently still without knowledge, how could it go astray and fall into the ruin of its present condition? Whence in general is the great discord that permeates this world? It may, further, be asked how deep into the true being of the world the roots of individuality go; to which it may certainly be answered: they go as deep as the assertion of the will to live; where the denial of the will appears they cease, for they have arisen with the assertion. But one might indeed even put the question, "What would I be if I were not will to live?" and more of the same kind. To

all such questions we would first have to reply that the expression of the most universal and general form of our intellect is the *principle of sufficient reason*; but that just on this account that principle finds application only to the phenomenon, not to the being in itself of things. Yet all whence and why depend upon that principle alone. As a result of the Kantian philosophy it is no longer an *æterna veritas*, but merely the form, *i.e.*, the function, of our intellect, which is essentially cerebral, and originally a mere tool in the service of the will, which it therefore presupposes together with all its objectifications. But our whole knowing and conceiving is bound to its forms; accordingly we must conceive everything in time, consequently as a before and after, then as cause and effect, and also as above and below, whole and part, &c., and cannot by any means escape from this sphere in which all possibility of our knowledge lies. Now these forms are utterly unsuited to the problems raised here, nor are they fit or able to comprehend their solution even if it were given. Therefore with our intellect, this mere tool of the will, we are everywhere striking upon insoluble problems, as against the walls of our prison. But, besides this, it may at least be assumed as probable that not only *for us* is knowledge of all that has been asked about impossible, but no such knowledge is possible in general, thus never and in no way; that these relations are not only relatively but absolutely insusceptible of investigation; that not only does no one know them, but that they are in themselves unknowable, because they do not enter into the form of knowledge in general. (This corresponds to what Scotus Erigena says, *de mirabili divina ignorantia, qua Deus non intelligit quid ipse sit*. Lib. ii.) For knowableness in general, with its most essential, and therefore constantly necessary form of subject and object, belongs merely to the phenomenal appearance, not to the being in itself of things. Where knowledge, and consequently idea, is, there is also only phenomenon, and we stand there already in the province of the phenomenal; nay, knowledge in general is known to us only as a phenomenon of brain, and we are not only unjustified in conceiving it otherwise, but also incapable of doing so. What the world is as world may be understood: it is phenomenal manifestation; and we can know that which manifests itself in it, directly from ourselves, by means of a thorough analysis of self-consciousness. Then, however, by means of this key to the nature of the world, the whole phenomenal manifestation can be deciphered, as I believe I have succeeded in doing. But if we leave the world in order to answer the questions

indicated above, we have also left the whole sphere in which, not only connection according to reason and consequent, but even knowledge itself is possible; then all is *instabilis tellus, innabilis unda*. The nature of things before or beyond the world, and consequently beyond the will, is open to no investigation; because knowledge in general is itself only a phenomenon, and therefore exists only in the world as the world exists only in it. The inner being in itself of things is nothing that knows, no intellect, but an unconscious; knowledge is only added as an accident, a means of assistance to the phenomenon of that inner being, and can therefore apprehend that being itself only in proportion to its own nature, which is designed with reference to quite different ends (those of the individual will), consequently very imperfectly. Here lies the reason why a perfect understanding of the existence, nature, and origin of the world, extending to its ultimate ground and satisfying all demands, is impossible. So much as to the limits of my philosophy, and indeed of all philosophy.

The ἐν και παν, *i.e.*, that the inner nature in all things is absolutely one and the same, my age had already grasped and understood, after the Eleatics, Scotus Erigena, Giordano Bruno, and Spinoza had thoroughly taught, and Schelling had revived this doctrine. But *what* this one is, and how it is able to exhibit itself as the many, is a problem the solution of which is first found in my philosophy. Certainly from the most ancient times man had been called the microcosm. I have reversed the proposition, and shown the world as the macranthropos: because will and idea exhaust its nature as they do that of man. But it is clearly more correct to learn to understand the world from man than man from the world; for one has to explain what is indirectly given, thus external perception from what is directly given, thus self-consciousness — not conversely.

With the Pantheists, then, I have certainly that ἐν και παν in common, but not the παν θεος; because I do not go beyond experience (taken in its widest sense), and still less do I put myself in contradiction with the data which lie before me. Scotus Erigena, quite consistently with the spirit of Pantheism, explains every phenomenon as a theophany; but then this conception must also be applied to the most terrible and abominable phenomena. Fine theophanies! What further distinguishes me from Pantheism is principally the following. (1). That their θεος is an *x*, an unknown quantity; the will, on the other hand, is of all possible things the one that is known to us most exactly, the only thing given immediately, and

therefore exclusively fitted for the explanation of the rest. For what is unknown must always be explained by what is better known; not conversely. (2). That their θεος manifests himself *animi causa*, to unfold his glory, or, indeed, to let himself be admired. Apart from the vanity here attributed to him, they are placed in the position of being obliged to sophisticate away the colossal evil of the world; but the world remains in glaring and terrible contradiction with that imagined excellence. With me, on the contrary, the *will* arrives through its objectification however this may occur, at self-knowledge, whereby its abolition, conversion, salvation becomes possible. And accordingly, with me alone ethics has a sure foundation and is completely worked out in agreement with the sublime and profound religions, Brahmanism, Buddhism, and Christianity, not merely with Judaism and Mohammedanism. The metaphysic of the beautiful also is first fully cleared up as a result of my fundamental truth, and no longer requires to take refuge behind empty words. With me alone is the evil of the world honestly confessed in its whole magnitude: this is rendered possible by the fact that the answer to the question as to its origin coincides with the answer to the question as to the origin of the world. On the other hand, in all other systems, since they are all optimistic, the question as to the origin of evil is the incurable disease, ever breaking out anew, with which they are affected, and in consequence of which they struggle along with palliatives and quack remedies. (3.) That I start from experience and the natural self-consciousness given to every one, and lead to the will as that which alone is metaphysical; thus I adopt the ascending, analytical method. The Pantheists, again, adopt the opposite method, the descending or synthetical. They start from their θεος, which they beg or take by force, although sometimes under the name *substantia*, or absolute, and this unknown is then supposed to explain everything that is better known. (4.) That with me the world does not fill the whole possibility of all being, but in this there still remains much room for that which we denote only negatively as the denial of the will to live. Pantheism, on the other hand, is essentially optimism: but if the world is what is best, then the matter may rest there. (5.) That to the Pantheists the perceptible world, thus the world of idea, is just the intentional manifestation of the God indwelling in it, which contains no real explanation of its appearance, but rather requires to be explained itself. With me, on the other hand, the world as idea appears merely *per accidens*, because the intellect, with its external perception, is primarily only the

medium of motives for the more perfect phenomena of will, which gradually rises to that objectivity of perceptibility, in which the world exists. In this sense its origin, as an object of perception, is really accounted for, and not, as with the Pantheists, by means of untenable fictions.

Since, in consequence of the Kantian criticism of all speculative theology, the philosophisers of Germany almost all threw themselves back upon Spinoza, so that the whole series of futile attempts known by the name of the post-Kantian philosophy are simply Spinozism tastelessly dressed up, veiled in all kinds of unintelligible language, and otherwise distorted, I wish, now that I have explained the relation of my philosophy to Pantheism in general, to point out its relation to Spinozism in particular. It stands, then, to Spinozism as the New Testament stands to the Old. What the Old Testament has in common with the New is the same God-Creator. Analogous to this, the world exists, with me as with Spinoza, by its inner power and through itself. But with Spinoza his *substantia æterna*, the inner nature of the world, which he himself calls God, is also, as regards its moral character and worth, Jehovah, the God-Creator, who applauds His own creation, and finds that all is very good, παντα καλα λιαν. Spinoza has deprived Him of nothing but personality. Thus, according to him also, the world and all in it is wholly excellent and as it ought to be: therefore man has nothing more to do than *vivere, agere, suum Esse conservare ex fundamento proprium utile quœrendi* (*Eth.*, iv. pr. 67); he is even to rejoice in his life as long as it lasts; entirely in accordance with Ecclesiastes ix. 7-10. In short, it is optimism: therefore its ethical side is weak, as in the Old Testament; nay, it is even false, and in part revolting.[54] With me, on the other hand, the will, or the inner nature of the world, is by no means Jehovah, it is rather, as it were, the crucified Saviour, or the crucified thief, according as it resolves. Therefore my ethical teaching agrees with that of Christianity, completely and in its highest tendencies, and not less with that of Brahmanism and Buddhism. Spinoza could not get rid of the Jews; *quo semel est imbuta recens servabit odorem*. His contempt for the brutes, which, as mere things for our use, he also declares to be without rights, is thoroughly Jewish, and, in union with Pantheism, is at the same time absurd and detestable (*Eth.*, iv., appendix, c. 27). With all this Spinoza remains a very great man. But in order to estimate his work correctly we must keep in view his relation to Descartes. The latter had sharply divided nature into mind and matter, *i.e.*, thinking and extended substance, and had also placed

God and the world in complete opposition to each other; Spinoza also, so long as he was a Cartesian, taught all that in his "*Cogitatis Metaphysicis*," c. 12, i. I., 1665. Only in his later years did he see the fundamental falseness of that double dualism; and accordingly his own philosophy principally consists of the indirect abolition of these two antitheses. Yet partly to avoid injuring his teacher, partly in order to be less offensive, he gave it a positive appearance by means of a strictly dogmatic form, although its content is chiefly negative. His identification of the world with God has also this negative significance alone. For to call the world God is not to explain it: it remains a riddle under the one name as under the other. But these two negative truths had value for their age, as for every age in which there still are conscious or unconscious Cartesians. He makes the mistake, common to all philosophers before Locke, of starting from conceptions, without having previously investigated their origin, such, for example, as substance, cause, &c., and in such a method of procedure these conceptions then receive a much too extensive validity. Those who in the most recent times refused to acknowledge the Neo-Spinozism which had appeared, for example, Jacobi, were principally deterred from doing so by the bugbear of fatalism. By this is to be understood every doctrine which refers the existence of the world, together with the critical position of mankind in it, to any absolute necessity, *i.e.*, to a necessity that cannot be further explained. Those who feared fatalism, again, believed that all that was of importance was to deduce the world from the free act of will of a being existing outside it; as if it were antecedently certain which of the two was more correct, or even better merely in relation to us. What is, however, especially assumed here is the *non datur tertium*, and accordingly hitherto every philosophy has represented one or the other. I am the first to depart from this; for I have actually established the *Tertium*: the act of will from which the world arises is our own. It is free; for the principle of sufficient reason, from which alone all necessity derives its significance, is merely the form of its phenomenon. Just on this account this phenomenon, if it once exists, is absolutely necessary in its course; in consequence of this alone we can recognise in it the nature of the act of will, and accordingly *eventualiter* will otherwise.

Appendix.

Abstract.

Schopenhauer's Essay on the Fourfold Root of the Principle of Sufficient Reason (Fourth Edition, Edited by Frauenstädt. The First Edition appeared in 1813).

This essay is divided into eight chapters. The first is introductory. The second contains an historical review of previous philosophical doctrines on the subject. The third deals with the insufficiency of the previous treatment of the principle, and prescribes the lines of the new departure. The fourth, fifth, sixth, and seventh treat of the four classes of objects for the subject, and the forms of the principle of sufficient reason which respectively characterise these classes. The eighth contains general remarks and results. It will be convenient to summarise these chapters severally.

Chapter I.

Schopenhauer points out that Plato and Kant agree in recommending, as the method of all knowledge, obedience to two laws: — that of Homogeneity, and that of Specification. The former bids us, by attention to the points of resemblance and agreement in things, get at their kinds, and combine them into species, and these species again into genera, until we have arrived at the highest concept of all, that which embraces everything. This law being transcendental, or an essential in our faculty of reason, assumes that nature is in harmony with it, an assumption which is expressed in the old rule: *Entia præter necessitatem non esse multiplicanda.* The law of Specification, on the other hand, is stated by Kant in these words: *Entium varietates non temere esse minuendas.* That is to say, we must carefully distinguish the species which are united under a genus, and the lower kinds which in their turn are united under these species; taking care not to make a leap, and subsume the lower kinds and individuals under the concept of the genus, since this is always capable of division, but never descends to the object of pure perception. Plato and Kant agree that these laws are transcendental, and that they presuppose that things are in harmony with them.

The previous treatment of the principle of sufficient reason, even by Kant, has been a failure, owing to the neglect of the second of these laws. It may well be that we shall find that this principle is the common expression of more than one fundamental principle of knowledge, and that the necessity, to which it refers, is therefore of different kinds. It may be stated in these words: *Nihil est sine ratione cur potius sit, quam non sit.* This is the general expression for the different forms of the assumption which everywhere justifies that question “Why?” which is the mother of all science.

Chapter II.

Schopenhauer in this chapter traces historically the forms in which the principle had been stated by his predecessors, and their influence. He points out that in Greek philosophy it appeared in two aspects — that of the necessity of a ground for a logical judgment, and that of a cause for every physical change — and that these two aspects were systematically confounded. The Aristotelian division, not of the forms of the principle itself, but of one of its aspects, the causal, exemplified a confusion which continued throughout the Scholastic period. Descartes succeeds no better. His proof of the existence of God that the immensity of His nature is a *cause or reason* beyond which no cause is needed for His existence, simply illustrates the gross confusion between cause and ground of knowledge which underlies every form of this ontological proof. "That a miserable fellow like Hegel, whose entire philosophy is nothing but a monstrous amplification of the ontological proof, should dare to defend this proof against Kant's criticism of it is an alliance of which the ontological proof itself, little as it knows of shame, might well feel ashamed. It is not to be expected I should speak respectfully of people who have brought philosophy into disrespect." Spinoza made the same confusion when he laid it down that the cause of existence was either contained in the nature and definition of the thing as it existed, or was to be found outside that thing. It was through this confusion of the ground of knowledge with the efficient cause that he succeeded in identifying God with the world. The true picture of Spinoza's "*Causa sui*" is Baron Munchhausen encircling his horse with his legs, and raising himself and the horse upwards by means of his pigtail, with the inscription "*Causa sui*" written below. Leibnitz was the first to place the principle of sufficient reason in the position of a first principle, and to indicate the difference between its two meanings. But it was Wolff who first completely distinguished them, and divided the doctrine into three kinds: *principium fiendi* (cause), *principium essendi* (possibility), and *principium cognoscendi*. Baumgarten, Reimarus, Lambert, and Platner added nothing to the work of Wolff, and the next great step was Hume's question as to the validity of the principle. Kant's distinction of the logical or formal principle of knowledge — Every *proposition* must have its ground; from the transcendental or material principle, Every *thing* must

have its ground — was followed out by his immediate successors. But when we come to Schelling we find the proposition that gravitation is the *reason* and light the *cause* of things, a proposition which is quoted simply as a curiosity, for such a piece of nonsense deserves no place among the opinions of earnest and honest inquirers. The chapter concludes by pointing out the futility of the attempts to prove the principle. Every proof is the exhibition of the ground of a judgment which has been expressed, and of which, just because that ground is exhibited, we predicate truth. The principle of sufficient reason is just this expression of the demand for such a ground, and he who seeks a proof, *i.e.*, the exhibition of a ground for this principle itself, presupposes it as true, and so falls into the circle of seeking a proof of the justification of the demand for proof.

Chapter III.

In the third chapter Schopenhauer points out that the two applications of the principle of sufficient reason distinguished by his predecessors, to judgments, which must have a ground, and to the changes of real objects, which must have a cause, are not exhaustive. The reason why the three sides of a certain triangle are equal is that the angles are equal, and this is neither a logical deduction nor a case of causation. With a view to stating exhaustively the various kinds into which the application of the principle falls it is necessary to determine the nature of the principle itself. All our ideas are objects of the subject, and all objects of the subject are our ideas. But our ideas stand to one another as a matter of fact in an orderly connection, which is always determinable *a priori* in point of form, and on account of which nothing that is in itself separate and wholly independent of other things can be the object of our consciousness. It is this connection which the principle of sufficient reason in its generality expresses. The relations which constitute it are what Schopenhauer calls its root, and they fall into four classes, which are discussed in the four following chapters.

Chapter IV.

In the fourth chapter Schopenhauer deals with the first class of objects for the subject and the form of the principle of sufficient reason which obtains in it. This first class is that of those complete ideas of perception which form part of our experience, and which are referable to some sensation of our bodies. These ideas are capable of being perceived only under the forms of Space and Time. If time were the only form there would be no coexistence, and therefore no persistence. If space were their only form there would be no succession, and therefore no change. Time may therefore be defined as the possibility of mutually exclusive conditions of the same thing. But the union of these two forms of existence is the essential condition of reality, and this union is the work of the understanding (see "World as Will and Idea," vol. i. § 4, and the table of predicables annexed to vol. ii., chap. 4). In this class of objects for the subject the principle of sufficient reason appears as the law of causality or the principle of sufficient reason of becoming, and it is through it that all objects which present themselves in perception are bound together through the changes of their states. When a new state of one or more objects makes its appearance it must have been preceded by another on which it regularly follows. This is causal sequence, and the first state is the cause, the second the effect. The law has thus to do exclusively with the *changes* of objects of external experience, and not with things themselves, a circumstance which is fatal to the validity of the cosmological proof of the existence of God. It follows also from the essential connection of causality with succession that the notion of reciprocity, with its contemporaneous existence of cause and effect, is a delusion. The chain of causes and effects does not affect either matter, which is that in which all changes take place, or the original forces of nature, through which causation becomes possible, and which exist apart from all change, and in this sense out of time, but which yet are everywhere present (*e.g.*, chemical forces, see *supra*, vol. i., § 26). In nature causation assumes three different forms; that of cause in the narrow sense, of stimulus, and of motive, on which differences depend the true distinctions between inorganic bodies, plants, and animals. It is only of cause properly so called that Newton's third law of the equality of action and reaction is true, and only here do we find the degree of the effect proportionate to that

of the cause. The absence of this feature characterises stimulation. Motive demands knowledge as its condition, and intelligence is therefore the true characteristic of the animal. The three forms are in principle identical, the difference being due to the degrees of receptivity in existence. What is called freedom of the will is therefore an absurdity, as is also Kant's "Practical Reason." These results are followed by an examination of the nature of vision, which Schopenhauer sums up in these words: "I have examined all these visual processes in detail in order to show that the understanding is active in all of them, the understanding which, by apprehending every change as an effect and referring it to its cause, creates on the basis of the *a priori* and fundamental intuitions or perceptions of space and time, the objective world, that phenomenon of the brain, for which the sensations of the senses afford only certain data. And this task the understanding accomplishes only through its proper form, the law of causality, and accomplishes it directly without the aid of reflection, that is, of abstract knowledge through concepts and words, which are the material of secondary knowledge, of thought, thus of the Reason." "What understanding knows aright is reality; what reason knows aright is truth, *i.e.*, a judgment which has a ground; the opposite of the former being illusion (what is falsely perceived), of the latter error (what is falsely thought)." All understanding is an immediate apprehension of the causal relation, and this is the sole function of understanding, and not the complicated working of the twelve Kantian Categories, the theory of which is a mistaken one. A consequence of this conclusion is, that arithmetical processes do not belong to the understanding, concerned as they are with abstract conceptions. But it must not be forgotten that between volition and the apparently consequential action of the body there is no causal relation, for they are the same thing perceived in two different ways. Section 23 contains a detailed refutation of Kant's proof of the *a priori* nature of the causal relation in the "Second Analogy of Experience" of the Critique of Pure Reason, the gist of the objection being that the so-called subjective succession is as much objective in reality as what is called objective by Kant: "Phenomena may well follow one another, without following *from* one another."

Chapter V.

The fifth chapter commences with an examination of the distinction between man and the brutes. Man possesses *reason*, that is to say, he has a class of ideas of which the brutes are not capable, *abstract* ideas as distinguished from those ideas of perception from which the former kind are yet derived. The consequence is, that the brute neither speaks nor laughs, and lacks all those qualities which make human life great. The nature of *motives*, too, is different where abstract ideas are possible. No doubt the actions of men follow of necessity from their causes, not less than is the case with the brutes, but the kind of sequence through thought which renders choice, *i.e.*, the conscious conflict of motives, possible is different. Our abstract ideas, being incapable of being objects of perception, would be outside consciousness, and the operations of thought would be impossible, were it not that they are fixed for sense by arbitrary signs called words, which therefore always indicate *general* conceptions. It is just because the brutes are incapable of general conceptions that they have no faculty of speech. But thought does not consist in the mere presence of abstract ideas in consciousness, but in the union and separation of two or more of them, subject to the manifold restrictions and modifications which logic deals with. Such a clearly expressed conceptual relation is a judgment. In relation to judgments the principle of sufficient reason is valid in a new form: that of the ground of knowing. In this form it asserts that if a judgment is to express knowledge it must have a ground; and it is just because it has a ground that it has ascribed to it the predicate true. The grounds on which a judgment may depend are divisible into four kinds. A judgment may have another judgment as its ground, in which case its truth is formal or *logical*. There is no truth except in the relation of a judgment to something outside it, and intrinsic truth, which is sometimes distinguished from extrinsic logical truth, is therefore an absurdity. A judgment may also have its ground in sense-perception, and its truth is then material truth. Again, those forms of knowledge which lie in the understanding and in pure sensibility, as the conditions of the possibility of experience, may be the ground of a judgment which is then synthetical *a priori*. Finally, those formal conditions of all thinking which lie in the reason may be the ground of a judgment, which may in that case be called metalogically true. Of these metalogical

judgments there are four, and they were long ago discovered and called laws of thought. (1.) A subject is equal to the sum of its predicates. (2.) A subject cannot at once have a given predicate affirmed and denied of it. (3.) Of two contradictorily opposed predicates one must belong to every subject. (4.) Truth is the relation of a judgment to something outside it as its sufficient reason. Reason, it may be remarked, has no material but only formal truth.

Chapter VI.

The third class of objects for the subject is constituted by the formal element in perception, the forms of outer and inner sense, space and time. This class of ideas, in which time and space appear as pure intuitions, is distinguished from that other class in which they are objects of perception by the presence of matter which has been shown to be the perceptibility of time and space in one aspect, and causality which has become objective, in another. Space and time have this property, that all their parts stand to one another in a relation in which each is determined and conditioned by another. This relation is peculiar, and is intelligible to us neither through understanding nor through reason, but solely through pure intuition or perception *a priori*. And the law according to which the parts of space and time thus determine one another is called the law of sufficient reason of *being*. In space every position is determined with reference to every other position, so that the first stands to the second in the relation of a consequence to its ground. In time every moment is conditioned by that which precedes it. The ground of being, in the form of the law of sequence, is here very simple owing to the circumstance that time has only one dimension. On the nexus of the position of the parts of space depends the entire science of geometry. Ground of *knowledge* produces *conviction* only, as distinguished from *insight* into the ground of being. Thus it is that the attempt, which even Euclid at times makes, to produce *conviction*, as distinguished from insight into the ground of being, in geometry, is a mistake, and induces aversions to mathematics in many an admirable mind.

Chapter VII.

The remaining class of objects for the subject is a very peculiar and important one. It comprehends only one object, the immediate object of inner sense, the subject in volition which becomes an object of knowledge, but only in inner sense, and therefore always in time and never in space; and in time only under limitations. There can be no knowledge of knowledge, for that would imply that the subject had separated itself from knowledge, and yet knew knowledge, which is impossible. The subject is the condition of the existence of ideas, and can never itself become idea or object. It knows itself therefore never as *knowing*, but only as *willing*. Thus what we know in ourselves is never what knows, but what wills, the will. The identity of the subject of volition with the subject of knowledge, through which the word "I" includes both, is the insoluble problem. The identity of the knowing with the known is inexplicable, and yet is immediately present. The operation of a motive is not, like that of all other causes, known only from without, and therefore indirectly, but also from within. Motivation is, in fact, causality viewed from within.

Chapter VIII.

In this, the concluding chapter, Schopenhauer sums up his results. Necessity has no meaning other than that of the irresistible sequence of the effect where the cause is given. All necessity is thus conditioned, and absolute or unconditioned necessity is a contradiction in terms. And there is a fourfold necessity corresponding to the four forms of the principle of sufficient reason: — (1.) The logical form, according to the principle of the ground of knowledge; on account of which, if the premisses are given, the conclusion follows. (2.) The physical form, according to the law of causality; on account of which, if the cause is given, the effect must follow. (3.) The mathematical form, according to the law of being; on account of which every relation expressed by a true geometrical proposition is what it is affirmed to be, and every correct calculation is irrefutable. (4.) The moral form, on account of which every human being and every brute must, when the motive appears, perform the only act which accords with the inborn and unalterable character. A consequence of this is, that every department of science has one or other of the forms of the principle of sufficient reason as its basis. In conclusion, Schopenhauer points out that just because the principle of sufficient reason belongs to the *a priori* element in intelligence, it cannot be applied to the entirety of things, to the universe as inclusive of intelligence. Such a universe is mere phenomenon, and what is only true because it belongs to the form of intelligence can have no application to intelligence itself. Thus it is that it cannot be said that the universe and all things in it exist because of something else. In other words, the cosmological proof of the existence of God is inadmissible.

ENDNOTES.

5.

Let me here remark in passing that, judging from the German literature since Kant, one would necessarily believe that Hume's whole wisdom had consisted in his obviously false scepticism with regard to the law of causality, for this alone is everywhere referred to. In order to know Hume one must read his "Natural History of Religion" and his "Dialogues on Natural Religion." There one sees him in his greatness, and these, together with Essay 21 "Of National Characters," are the writings on account of which — I know of nothing that says more for his fame — even to the present day, he is everywhere hated by the English clergy.

7.

In the *Siècle*, 10th April 1859, there appears, very beautifully written, the story of a squirrel that was magically drawn by a serpent into its very jaws: "Un voyageur qui vient de parcourir plusieurs provinces de l'ile de Java cite un exemple remarqueable du pouvoir facinateur des serpens. Le

voyageur dont il est question commençait à gravir Junjind, un des monts appelés par les Hollandais Pepergebergte. Après avoir pénétré dans une épaisse forêt, il aperçut sur les branches d'un kijatile un écureuil de Java à tête blanche, folâtrant avec la grâce et l'agilité qui distinguent cette charmante espèce de rongeurs. Un nid sphérique, formé de brins flexible et de mousse, placé dans les parties les plus élevées de l'arbre, a l'enfourchure de deux branches, et une cavité dans le tronc, semblaient les points de mire de ses jeux. A peine s'en était-il éloigné qu'il y revenait avec une ardeur extrême. On était dans le mois de Juillet, et probablement l'écureuil avait en haut ses petits, et dans le bas le magasin à fruits. Bientôt il fut comme saisi d'effroi, ces mouvemens devinrent désordonnés, on eut dit qu'il cherchait toujours à mettre un obstacle entre lui et certaines parties de l'arbre: puis il se tapit et resta immobile entre deux branches. Le voyageur eut le sentiment d'un danger pour l'innocente bête, mais il ne pouvait deviner lequel. Il approcha, et un examen attentif lui fit découvrir dans un creux du tronc une couleuvre lieu, dardant ses yeux fixes dans la direction de l'écureuil. Notre voyageur trembla pour le pauvre écureuil. La couleuvre était si attentive à sa proie qu'elle ne semblait nullement remarquer la présence d'un homme. Notre voyageur, qui était armé, aurait donc prevenir en aide à l'infortuné rongeur en tuant le serpent. Mais la science l'emporta sur la pitié, et il voulut voir quelle issue aurait le drame. Le dénoûment fut tragique. L'écureuil ne tarda point à pousser un cri plaintif qui, pour tous ceux qui le connaissent, dénote le voisinage d'un serpent. Il avança un peu, essaya de reculer, revint encore en avant, tâche de retourner en arrière. Mais s'approcha toujours plus du reptile. La couleuvre, roulée en spirale, la tête au dessus des anneaux, et immobile comme un morceau de bois, ne le quittait pas du regard. L'écureuil, de branche en branche, et descendant toujours plus bas, arriva jusqu'à la partie nue du tronc. Alors le pauvre animal ne tenta même plus de fuir le danger. Attiré par une puissance invincible, et comme poussé par le vertige, il se précipita dans la gueule du serpent, qui s'ouvrit tout à coup démesurément pour le recevoir. Autant la couleuvre avait été inerte jusque là autant elle devint active dès qu'elle fut en possession de sa proie. Déroulant ses anneaux et prenant sa course de bas en haut avec une agilité inconcevable, sa reptation la porta en un clin d'œil au sommet de l'arbre, où elle alla sans doute digérer et dormir."

In this example we see what spirit animates nature, for it reveals itself in it, and how very true is the saying of Aristotle quoted above (p. 106). This story is not only important with regard to fascination, but also as an argument for pessimism. That an animal is surprised and attacked by another is bad; still we can console ourselves for that; but that such a poor innocent squirrel sitting beside its nest with its young is compelled, step by step, reluctantly, battling with itself and lamenting, to approach the wide, open jaws of the serpent and consciously throw itself into them is revolting and atrocious. What monstrous kind of nature is this to which we belong!

24.

Let me remark in passing that from this opposition of ποιησις and ἱστορια the origin, and also the peculiar significance, of the first word comes out with more than ordinary distinctness; it signifies that which is made, invented, in opposition to what is discovered.

25.

This chapter is connected with § 52 of the first volume.

26.

It would be a false objection that sculpture and painting are also merely in space; for their works are connected, not directly, but yet indirectly, with time, for they represent life, movement, action. And it

would be just as false to say that poetry, as speech, belongs to time alone: this is also true only indirectly of the words; its matter is all existent, thus spatial.

27.

28.

In gladiatoriis pugnis timidos et supplices, et, ut vivere liceat, obsecrantes etiam odisse solemus; fortes et animosos, et se acriter ipsos morti offerentes servare cupimus (*Cic. pro Milone*, c. 34).

29.

The suspension of the *animal* functions is sleep, that of the *organic* functions is death.

30.

There is only *one present*, and this is always: for it is the sole form of actual existence. One must attain to the insight that the *past* is not *in itself* different from the present, but only in our apprehension, which has time as its form, on account of which alone the present exhibits itself as different from the past. To assist this insight, imagine all the events and scenes of human life, bad and good, fortunate and unfortunate, pleasing and terrible, as they successively present themselves in the course of time and difference of places, in the most checkered multifariousness and variety, as *at once and together*, and always present in the *Nunc stans*, while it is only apparently that now this and now that is; then what the objectification of the will to live really means will be understood. Our pleasure also in *genre* painting depends principally upon the fact that it fixes the fleeting scenes of life. The dogma of metempsychosis has proceeded from the feeling of the truth which has just been expressed.

31.

This posthumous essay is to be found in the “Essays on Suicide and the Immortality of the Soul” by the late David Hume, Basil, 1799, sold by James Decker. By this reprint at Bâle these two works of one of the greatest thinkers and writers of England were rescued from destruction, when in their own land, in consequence of the stupid and utterly contemptible bigotry which prevailed, they had been suppressed through the influence of a powerful and insolent priesthood, to the lasting shame of England. They are entirely passionless, coldly rational investigations of the two subjects named.

32.

Death says: Thou art the product of an act which should not have been; therefore to expiate it thou must die.

34.

The etymology of the word Nirvana is variously given. According to Colebrooke ("Transact. of the Royal Asiat. Soc.," vol. i. p. 566) it comes from *va*, "to blow," like the wind, and the prefixed negative *nir*, and thus signifies a calm, but as an adjective "extinguished." Obry, also, *Du Nirvana Indien*, p. 3, says: "*Nirvanam en sanscrit signifie à la lettre extinction, telle que celle d'un feu*." According to the "Asiatic Journal," vol. xxiv. p. 735, the word is really Neravana, from *nera*, "without," and *vana*, "life," and the meaning would be *annihilatio*. In "Eastern Monachism," by Spence Hardy, p. 295, Nirvana is derived from *vana*, "sinful desires," with the negative *nir*. J. J. Schmidt, in his translation of the history of the Eastern Mongolians, says that the Sanscrit word Nirvana is translated into Mongolian by a phrase which signifies "departed from misery," "escaped from misery." According to the learned lectures of the same in the St. Petersburg Academy, Nirvana is the opposite of Sanfara, which is the world of constant re-birth, of longings and desires, of illusion of the senses and changing forms, of being born, growing old, becoming sick, and dying. In the Burmese language the word Nirvana, according to the analogy of other Sanscrit words, becomes transformed into Nieban, and is translated by "complete vanishing." See Sangermano's "Description of the Burmese Empire," translated by Tandy, Rome, 1833, § 27. In the first edition of 1819 I also wrote Nieban, because we then knew Buddhism only from meagre accounts of the Burmese.

36.

Lichtenberg says in his miscellaneous writings (Göttingen, 1801, vol. ii. p. 447): "In England it was proposed to castrate thieves. The proposal is not bad: the punishment is very severe; it makes persons contemptible, and yet leaves them still fit for trades; and if stealing is hereditary, in this way it is not

propagated. Moreover, the courage ceases, and since the sexual passion so frequently leads to thefts, this cause would also disappear. The remark that women would so much the more eagerly restrain their husbands from stealing is roguish, for as things are at present they risk losing them altogether."

37.

I have not ventured to express myself distinctly here: the courteous reader must therefore translate the phrase into Aristophanic language.

38.

The fuller discussion of this subject will be found in the "Parerga," vol. ii. § 92 of the first edition (second edition, pp. 167-170).

39.

[The appendix to this chapter was added only in the third edition of the German, and is meant to explain, in consistency with Schopenhauer's general principles, the wide prevalence of the practice of pederasty, among different nations and in different ages. It is omitted. — *Trs.*]

40.

This chapter is connected with § 60 of the first volume.

41.

This chapter is connected with §§ 56-59 of the first volume. Also chapters 11 and 12 of the second volume of the "Parerga and Paralipomena" should be compared with it.

42.

All that we lay hold of resists us because it has its own will, which must be overcome.

43.

This chapter is connected with §§ 55, 62, 67 of the first volume.

44.

This chapter is connected with § 68 of the first volume. Chapter 14 of the second volume of the Parerga should also be compared with it.

45.

If, on the contrary, asceticism is admitted, the list of the ultimate motives of human action, given in my prize essay on the foundation of morals, namely: (1) our own good, (2) the ill of others, and (3) the good of others, must be supplemented by a fourth, our own ill; which I merely mention here in passing in the interests of systematic consistency. In the essay referred to this fourth motive had to be passed over in silence, for the question asked was stated in the spirit of the philosophical ethics prevailing in Protestant Europe.

48.

If we keep in view the essential immanence of our knowledge and of all knowledge, which arises from the fact that it is a secondary thing which has only appeared for the ends of the will, it then becomes explicable to us that all mystics of all religions ultimately attain to a kind of ecstasy, in which all and every knowledge, with its whole fundamental form, object and subject, entirely ceases, and only in this sphere, which lies beyond all knowledge, do they claim to have reached their highest goal, for they have then attained to the sphere in which there is no longer any subject and object, and consequently no more knowledge, just because there is no more will, the service of which is the sole destiny of knowledge.

Now, whoever has comprehended this will no longer regard it as beyond all measure extravagant that Fakirs should sit down, and, contemplating the tip of their nose, seek to banish all thought and perception, and that in many passages of the Upanischads instructions are given to sink oneself, silently and inwardly pronouncing the mysterious Oum, in the depths of one's own being, where subject and object and all knowledge disappear.

Matt. xix. 11 *seq.*; Luke xx. (1 Thess. iv. 3; 1 John iii. 3); Rev. 35-37; 1 Cor. vii. 1-11 and 25-40, xiv. 4.

52.

Cf. "*Ueber den Willen in der Natur*," second edition, p. 124; third edition, p. 135.

53.

For example, John xii. 25, 31, xiv. 30, xv. 18, 19, xvi. 33; Col. ii. 20; Eph. ii. 1-3; I John ii. 15-17, iv. 4, 5. On this opportunity one may see how certain Protestant theologians, in their efforts to misinterpret the text of the New Testament in conformity with their rationalistic, optimistic, and unutterably shallow view of life, go so far that they actually falsify this text in their translations. Thus H. A. Schott, in his new version given with the Griesbach text of 1805, has translated the word κοσμος, John xv. 18, 19, by *Judæi*, 1 John iv. 4, by *profani homines*; and Col. ii. 20, στοιχεια του κοσμον by *elementa Judaica*; while Luther everywhere renders the word honestly and correctly by "*Welt*" (world).

54.

Unusquisque tantum juris habet, quantum potentiâ valet (*Tract. pol.*, c. 2 § 8). *Fides alicui data tamdiu rata manet, quamdiu ejus, qui fidem dedit, non mutatur voluntas* (*Ibid.*, § 12). *Uniuscujusque jus potentiâ ejus definetur* (*Eth.* iv., *pr.* 37, *schol.* 1.) Especially chap. 16 of the *Tractatus theologico-politicus* is the true compendium of the immorality of Spinoza's philosophy.

THE ART OF BEING RIGHT

38 WAYS TO WIN AN ARGUMENT

Translated by T. Bailey Saunders

The Art of Being Right: 38 Ways to Win an Argument is a satirical treatise, examining thirty-eight methods of showing up one's opponent in a debate. Schopenhauer introduces his essay with the idea that philosophers have concentrated in ample measure on the rules of logic, but have not (especially since the time of Immanuel Kant) engaged with the darker art of the dialectic and controversy. Whereas the purpose of logic is classically said to be a method of arriving at the truth, dialectic, Schopenhauer claims, "would treat of the intercourse between two rational beings who, because they are rational, ought to think in common, but who, as soon as they cease to agree like two clocks keeping exactly the same time, create a disputation, or intellectual contest."

Schopenhauer presents all the sophistic tricks so frequently occurring in argument, clearly presenting each in its characteristic setting, illustrated by examples and given a name of its own. He also offers advice to be used against these techniques, as a form of safeguard in philosophical debate. However, when Schopenhauer later revised the text, he found "that such a detailed and minute consideration of the crooked ways and tricks that are used by common human nature to cover up its shortcomings is no longer suited to my temperament and so I lay it aside." He then recorded a few stratagems as specimens for anyone in the future that might care to write a similar essay.

CONTENTS

The Extension

The Extension. — This consists in carrying your opponent's proposition beyond its natural limits; in giving it as general a signification and as wide a sense as possible, so as to exaggerate it; and, on the other hand, in giving your own proposition as restricted a sense and as narrow limits as you can, because the more general a statement becomes, the more numerous are the objections to which it is open. The defence consists in an accurate statement of the point or essential question at issue.

Example 1. — I asserted that the English were supreme in drama. My opponent attempted to give an instance to the contrary, and replied that it was a well-known fact that in music, and consequently in opera, they could do nothing at all. I repelled the attack by reminding him that music was not included in dramatic art, which covered tragedy and comedy alone. This he knew very well. What he had done was to try to generalise my proposition, so that it would apply to all theatrical representations, and, consequently, to opera and then to music, in order to make certain of defeating me. Contrarily, we may save our proposition by reducing it within narrower limits than we had first intended, if our way of expressing it favours this expedient.

Example 2. — A. declares that the Peace of 1814 gave back their independence to all the German towns of the Hanseatic League. B. gives an instance to the contrary by reciting the fact that Dantzig, which received its independence from Buonaparte, lost it by that Peace. A. saves himself thus: "I said 'all German towns,' and Dantzig was in Poland."

This trick was mentioned by Aristotle in the Topica (bk. viii., cc. 11, 12).

Example 3. — Lamarck, in his Philosophie Zoologique (vol. i.,), states that the polype has no feeling, because it has no nerves. It is certain, however, that it has some sort of perception; for it advances towards light by moving in an ingenious fashion from branch to branch, and it seizes its prey. Hence it has been assumed that its nervous system is spread over the whole of its body in equal measure, as though it were blended with it; for it is obvious that the polype possesses some faculty of perception without having any separate organs of sense. Since this assumption refutes

Lamarck's position, he argues thus: "In that case all parts of its body must be capable of every kind of feeling, and also of motion, of will, of thought. The polype would have all the organs of the most perfect animal in every point of its body; every point could see, smell, taste, hear, and so on; nay, it could think, judge, and draw conclusions; every particle of its body would be a perfect animal, and it would stand higher than man, as every part of it would possess all the faculties which man possesses only in the whole of him. Further, there would be no reason for not extending what is true of the polype to all monads, the most imperfect of all creatures, and ultimately to the plants, which are also alive, etc., etc." By using dialectical tricks of this kind a writer betrays that he is secretly conscious of being in the wrong. Because it was said that the creature's whole body is sensitive to light, and is therefore possessed of nerves, he makes out that its whole body is capable of thought.

The Homonymy

The *Homonymy*. — This trick is to extend a proposition to something which has little or nothing in common with the matter in question but the similarity of the word; then to refute it triumphantly, and so claim credit for having refuted the original statement.

It may be noted here that synonyms are two words for the same conception; homonyms, two conceptions which are covered by the same word. (See Aristotle, Topica, bk. i., c. 13.) “Deep,” “cutting,” “high,” used at one moment of bodies, at another of tones, are homonyms; “honourable” and “honest” are synonyms.

This is a trick which may be regarded as identical with the sophism ex homonymia; although, if the sophism is obvious, it will deceive no one.

Every light can be extinguished.
The intellect is a light.
Therefore it can, be extinguished.

Here it is at once clear that there are four terms in the syllogism, “light” being used both in a real and in a metaphorical sense. But if the sophism takes a subtle form, it is, of course, apt to mislead, especially where the conceptions which are covered by the same word are related, and inclined to be interchangeable. It is never subtle enough to deceive, if it is used intentionally; and therefore cases of it must be collected from actual and individual experience.

It would be a very good thing if every trick could receive some short and obviously appropriate name, so that when a man used this or that particular trick, he could be at once reproached for it.

I will give two examples of the homonymy.

Example 1 — A.: “You are not yet initiated into the mysteries of the Kantian philosophy.”

B.: “Oh, if it’s mysteries you’re talking of, I’ll have nothing to do with them.”

Example 2. — I condemned the principle involved in the word honour as a foolish one; for, according to it, a man loses his honour by receiving all insult, which he cannot wipe out unless he replies with a still greater insult,

or by shedding his adversary’s blood or his own. I contended that a man’s true honour cannot be outraged by what he suffers, but only and alone by what he does; for there is no saying what may befall any one of us. My opponent immediately attacked the reason I had given, and triumphantly proved to me that when a tradesman was falsely accused of misrepresentation, dishonesty, or neglect in his business, it was an attack upon his honour, which in this case was outraged solely by what he suffered, and that he could only retrieve it by punishing his aggressor and making him retract.

Here, by a homonymy, he was foisting civic honour, which is otherwise called good name, and which may be outraged by libel and slander, on to the conception of knightly honour, also called point d’honneur, which may be outraged by insult. And since an attack on the former cannot be disregarded, but must be repelled by public disproof, so, with the same justification, an attack on the latter must not be disregarded either, but it must be defeated by still greater insult and a duel. Here we have a confusion of two essentially different things through the homonymy in the word honour, and a consequent alteration of the point in dispute.

Generalize your Opponent's Specific Statements

Another trick is to take a proposition which is laid down relatively, and in reference to some particular matter, as though it were uttered with a general or absolute application; or, at least, to take it in some quite different sense, and then refute it. Aristotle's example is as follows:

A Moor is black; but in regard to his teeth he is white; therefore, he is black and not black at the same moment. This is an obvious sophism, which will deceive no one. Let us contrast it with one drawn from actual experience.

In talking of philosophy, I admitted that my system upheld the Quietists, and commended them. Shortly afterwards the conversation turned upon Hegel, and I maintained that his writings were mostly nonsense; or, at any rate, that there were many passages in them where the author wrote the words, and it was left to the reader to find a meaning for them. My opponent did not attempt to refute this assertion ad rem, but contented himself by advancing the argumentum ad hominem and telling me that I had just been praising the Quietists, and that they had written a good deal of nonsense too.

This I admitted; but, by way of correcting him, I said that I had praised the Quietists, not as philosophers and writers, that is to say, for their achievements in the sphere of theory, but only as men, and for their conduct in mere matters of practice; and that in Hegel's case we were talking of theories. In this way I parried the attack.

The first three tricks are of a kindred character. They have this in common, that something different is attacked from that which was asserted. It would therefore be an ignoratio elenchi to allow oneself to be disposed of in such a manner.

For in all the examples that I have given, what the opponent says is true, but it stands in apparent and not in real contradiction with the thesis. All that the man whom he is attacking has to do is to deny the validity of his syllogism; to deny, namely, the conclusion which he draws, that because his proposition is true, ours is false. In this way his refutation is itself directly refuted by a denial of his conclusion, per negationem consequentiae. Another trick is to refuse to admit true premisses because of a foreseen

conclusion. There are two ways of defeating it, incorporated in the next two sections.

Conceal Your Game

If you want to draw a conclusion, you must not let it be foreseen, but you must get the premisses admitted one by one, unobserved, mingling them here and there in your talk: otherwise, your opponent will attempt all sorts of chicanery. Or, if it is doubtful whether your opponent will admit them, you must advance the premisses of these premisses; that is to say, you must draw up pro-syllogisms, and get the premisses of several of them admitted in no definite order. In this way you conceal your game until you have obtained all the admissions that are necessary, and so reach your goal by making a circuit. These rules are given by Aristotle in his Topica, bk. viii., c. 1. It is a trick which needs no illustration.

False Propositions

To prove the truth of a proposition, you may also employ previous propositions that are not true, should your opponent refuse to admit the true ones, either because he fails to perceive their truth, or because he sees that the thesis immediately follows from them. In that case the plan is to take propositions which are false in themselves but true for your opponent, and argue from the way in which he thinks, that is to say, ex concessis. For a true conclusion may follow from false premisses, but not vice versâ. In the same fashion your opponent's false propositions may be refuted by other false propositions, which he, however takes to be true; for it is with him that you have to do, and you must use the thoughts that he uses. For instance, if he is a member of some sect to which you do not belong, you may employ the declared opinions of this sect against him, as principles.

Postulate What Has To Be Proved

Another plan is to beg the question in disguise by postulating what has to be proved, either (1) under another name; for instance, “good repute” instead of “honour”; “virtue” instead of “virginity,” etc.; or by using such convertible terms as “red-blooded animals” and “vertebrates”; or (2) by making a general assumption covering the particular point in dispute: for instance, maintaining the uncertainty of medicine by postulating the uncertainty of all human knowledge. (3) If, vice versâ two things follow one from the other, and one is to be proved, you may postulate the other. (4) If a general proposition is to be proved, you may get your opponent to admit every one of the particulars. This is the converse of the second.

Yield Admissions Through Questions

Should the disputation be conducted on somewhat strict and formal lines, and there be a desire to arrive at a very clear understanding, he who states the proposition and wants to prove it may proceed against his opponent by question, in order to show the truth of the statement from his admissions. This erotematic, or Socratic, method was especially in use among the ancients; and this and some of the tricks following later on are akin to it.

The plan is to ask a great many wide-reaching questions at once, so as to hide what you want to get admitted, and, on the other hand, quickly propound the argument resulting from the admissions; for those who are slow of understanding cannot follow accurately, and do not notice any mistakes or gaps there may be in the demonstration.

Make Your Opponent Angry

This trick consists in making your opponent angry; for when he is angry he is incapable of judging aright, and perceiving where his advantage lies. You can make him angry by doing him repeated injustice, or practising some kind of chicanery, and being generally insolent.

Questions in Detouring Order

Or you may put questions in an order different from that which the conclusion to be drawn from them requires, and transpose them, so as not to let him know at what you are aiming. He can then take no precautions. You may also use his answers for different or even opposite conclusions, according to their character. This is akin to the trick of masking your procedure.

Take Advantage of The Nay-Sayer

If you observe that your opponent designedly returns a negative answer to the questions which, for the sake of your proposition, you want him to answer in the affirmative, you must ask the converse of the proposition, as though it were that which you were anxious to see affirmed; or, at any rate, you may give him his choice of both, so that he may not perceive which of them you are asking him to affirm.

Generalize Admissions of Specific Cases

If you make an induction, and your opponent grants you the particular cases by which it is to be supported, you must refrain from asking him if he also admits the general truth which issues from the particulars, but introduce it afterwards as a settled and admitted fact; for, in the meanwhile, he will himself come to believe that he has admitted it, and the same impression will be received by the audience, because they will remember the many questions as to the particulars, and suppose that they must, of course, have attained their end.

Choose Metaphors Favourable to Your Proposition

If the conversation turns upon some general conception which has no particular name, but requires some figurative or metaphorical designation, you must begin by choosing a metaphor that is favourable to your proposition. For instance, the names used to denote the two political parties in Spain, Serviles and Liberales, are obviously chosen by the latter. The name Protestants is chosen by themselves, and also the name Evangelicals; but the Catholics call them heretics. Similarly, in regard to the names of things which admit of a more exact and definite meaning: for example, if your opponent proposes an alteration, you can call it an innovation, as this is an invidious word. If you yourself make the proposal, it will be the converse. In the first case, you can call the antagonistic principle "the existing order," in the second, "antiquated prejudice". What an impartial man with no further purpose to serve would call "public worship" or a "system of religion," is described by an adherent as "piety," "godliness"; and by an opponent as "bigotry," "superstition". This is, at bottom, a subtle petitio principii. What is sought to be proved is, first of all, inserted in the definition, whence it is then taken by mere analysis. What one man calls "placing in safe custody," another calls "throwing into prison". A speaker often betrays his purpose beforehand by the names which he gives to things. One may talks of "the clergy"; another, of "the priests".

Of all the tricks of controversy, this is the most frequent, and it is used instinctively. You hear of "religious zeal," or "fanaticism", a "faux pas," a "piece of gallantry," or "adultery"; an "equivocal," or a "bawdy" story; "embarrassment," or "bankruptcy"; "through influence and connection," or by "bribery and nepotism"; "sincere gratitude," or "good pay".

Agree to Reject the Counter-Proposition

To make your opponent accept a proposition, you must give him the counter-proposition as well, leaving him his choice of the two; and you must render the contrast as glaring as you can, so that to avoid being paradoxical he will accept the proposition, which is thus made to look quite probable. For instance, if you want to make him admit that a boy must do everything that his father tells him to do, ask him "whether in all things we must obey or disobey our parents". Or, if a thing is said to occur "often," ask whether by "often" you are to understand few or many cases; and he will say "many". It is as though you were to put grey next to black, and call it white; or next to white, and call it black.

Claim Victory Despite Defeat

This, which is an impudent trick, is played as follows: When your opponent has answered several of your questions without the answers turning out favourable to the conclusion at which you are aiming, advance the desired conclusion, — although it does not in the least follow, — as though it had been proved, and proclaim it in a tone of triumph. If your opponent is shy or stupid, and you yourself possess a great deal of impudence and a good voice, the trick may easily succeed. It is akin to the fallacy non causae ut causae.

Use Seemingly Absurd Propositions

If you have advanced a paradoxical proposition and find a difficulty in proving it, you may submit for your opponent's acceptance or rejection some true proposition, the truth of which, however, is not quite palpable, as though you wished to draw your proof from it. Should he reject it because he suspects a trick, you can obtain your triumph by showing how absurd he is; should he accept it, you have got reason on your side for the moment, and must now look about you; or else you can employ the previous trick as well, and maintain that your paradox is proved by the proposition which he has accepted. For this an extreme degree of impudence is required; but experience shows cases of it, and there are people who practise it by instinct.

Arguments Ad Hominem

Another trick is to use arguments ad hominem, or ex concessis. When your opponent makes a proposition, you must try to see whether it is not in some way — if needs be, only apparently — inconsistent with some other proposition which he has made or admitted, or with the principles of a school or sect which he has commended and approved, or with the actions of those who support the sect, or else of those who give it only an apparent and spurious support; or with his own actions or want of action. For example, should he defend suicide, you may at once exclaim, “Why don’t you hang yourself?” Should he maintain that Berlin is an unpleasant place to live in, you may say, “Why don’t you leave by the first train?” Some such claptrap is always possible.

Defense Through Subtle Distinction

If your opponent presses you with a counter-proof, you will often be able to save yourself by advancing some subtle distinction, which, it is true, had not previously occurred to you; that is, if the matter admits of a double application, or of being taken in any ambiguous sense.

Interrupt, Break, Divert the Dispute

If you observe that your opponent has taken up a line of argument which will end in your defeat, you must not allow him to carry it to its conclusion, but interrupt the course of the dispute in time, or break it off altogether, or lead him away from the subject, and bring him to others. In short, you must effect the trick which will be noticed later on, the mutatio controversiae.

Generalize the Matter, Then Argue Against it

Should your opponent expressly challenge you to produce any objection to some definite point in his argument, and you have nothing much to say, you must try to give the matter a general turn, and then talk against that. If you are called upon to say why a particular physical hypothesis cannot be accepted, you may speak of the fallibility of human knowledge, and give various illustrations of it.

Draw Conclusions Yourself

When you have elicited all your premisses, and your opponent has admitted them, you must refrain from asking him for the conclusion, but draw it at once for yourself; nay, even though one or other of the premisses should be lacking, you may take it as though it too had been admitted, and draw the conclusion. This trick is an application of the fallacy non causae ut causae.

Meet him With a Counter-Argument as Bad as His

When your opponent uses a merely superficial or sophistical argument and you see through it, you can, it is true, refute it by setting forth its captious and superficial character; but it is better to meet him with a counter-argument which is just as superficial and sophistical, and so dispose of him; for it is with victory that you are concerned, and not with truth. If, for example, he adopts an argumentum ad hominem, it is sufficient to take the force out of it by a counter argumentum ad hominem or argumentum ex concessis; and, in general, instead of setting forth the true state of the case at equal length, it is shorter to take this course if it lies open to you.

Petitio principii

If your opponent requires you to admit something from which the point in dispute will immediately follow, you must refuse to do so, declaring that it is a petitio principii. For he and the audience will regard a proposition which is near akin to the point in dispute as identical with it, and in this way you deprive him of his best argument.

Make Him Exaggerate his Statement

Contradiction and contention irritate a man into exaggerating his statement. By contradicting your opponent you may drive him into extending beyond its proper limits a statement which, at all events within those limits and in itself, is true; and when you refute this exaggerated form of it, you look as though you had also refuted his original statement. Contrarily, you must take care not to allow yourself to be misled by contradiction into exaggerating or extending a statement of your own. It will often happen that your opponent will himself directly try to extend your statement further than you meant it; here you must at once stop him, and bring him back to the limits which you set up: "That's what I said, and no more".

State a False Syllogism

This trick consists in stating a false syllogism. Your opponent makes a proposition, and by false inference and distortion of his ideas you force from it other propositions which it does not contain and he does not in the least mean; nay, which are absurd or dangerous. It then looks as if his proposition gave rise to others which are inconsistent either with themselves or with some acknowledged truth, and so it appears to be indirectly refuted. This is the diversion, and it is another application of the fallacy non causae ut causae.

Find One Instance to The Contrary

This is a case of the diversion by means of an instance to the contrary. With an induction (epagoge), a great number of particular instances are required in order to establish it as a universal proposition; but with the diversion (apagoge) a single instance, to which the proposition does not apply, is all that is necessary to overthrow it. This is a controversial method known as the instance — instantia, eustasis. For example, “all ruminants are horned” is a proposition which may be upset by the single instance of the camel. The instance is a case in which a universal truth is sought to be applied, and something is inserted in the fundamental definition of it which is not universally true, and by which it is upset. But there is room for mistake; and when this trick is employed by your opponent, you must observe (1) whether the example which he gives is really true; for there are problems of which the only true solution is that the case in point is not true — for example, many miracles, ghost stories, and so on: and (2) whether it really comes under the conception of the truth thus stated: for it may only appear to do so, and the matter is one to be settled by precise distinctions; and (3) whether it is really inconsistent with this conception; for this again may be only an apparent inconsistency.

Turn The Tables

A brilliant move is the retorsio argumenti, or turning of the tables, by which your opponent's argument is turned against himself. He declares, for instance, "So-and-so is a child, you must make allowance for him". You retort, "Just because he is a child, I must correct him; otherwise he will persist in his bad habits".

Anger Indicates a Weak Point

Should your opponent surprise you by becoming particularly angry at an argument, you must urge it with all the more zeal; not only because it is a good thing to make him angry, but because it may be presumed that you have here put your finger on the weak side of his case, and that just here he is more open to attack than even for the moment you perceive.

Persuade the Audience, Not The Opponent

This is chiefly practicable in a dispute between scholars in the presence of the unlearned. If you have no argument ad rem, and none either ad hominem, you can make one ad auditores; that is to say, you can start some invalid objection, which, however, only an expert sees to be invalid. Now your opponent is an expert, but those who form your audience are not, and accordingly in their eyes he is defeated; particularly if the objection which you make places him in any ridiculous light. People are ready to laugh, and you have the laughers on your side. To show that your objection is an idle one, would require a long explanation on the part of your opponent, and a reference to the principles of the branch of knowledge in question, or to the elements of the matter which you are discussing; and people are not disposed to listen to it. For example, your opponent states that in the original formation of a mountain-range the granite and other elements in its composition were, by reason of their high temperature, in a fluid or molten state; that the temperature must have amounted to some 480 degrees Fahrenheit; and that when the mass took shape it was covered by the sea. You reply, by an argument ad auditores, that at that temperature — nay, indeed, long before it had been reached, namely, at 212 degrees Fahrenheit — the sea would have been boiled away, and spread through the air in the form of steam. At this the audience laughs. To refute the objection, your opponent would have to show that the boiling-point depends not only on the degree of warmth, but also on the atmospheric pressure; and that as soon as about half the sea-water had gone off in the shape of steam, this pressure would be so greatly increased that the rest of it would fail to boil even at a temperature of 480 degrees. He is debarred from giving this explanation, as it would require a treatise to demonstrate the matter to those who had no acquaintance with physics.

Diversion

If you find that you are being worsted, you can make a diversion — that is, you can suddenly begin to talk of something else, as though it had a bearing on the matter in dispute, and afforded an argument against your opponent. This may be done without presumption if the diversion has, in fact, some general bearing on the matter; but it is a piece of impudence if it has nothing to do with the case, and is only brought in by way of attacking your opponent.

For example, I praised the system prevailing in China, where there is no such thing as hereditary nobility, and offices are bestowed only on those who succeed in competitive examinations. My opponent maintained that learning, as little as the privilege of birth (of which he had a high opinion), fits a man for office. We argued, and he got the worst of it. Then he made a diversion, and declared that in China all ranks were punished with the bastinado, which he connected with the immoderate indulgence in tea, and proceeded to make both of them a subject of reproach to the Chinese. To follow him into all this would have been to allow oneself to be drawn into a surrender of the victory which had already been won. The diversion is mere impudence if it completely abandons the point in dispute, and raises, for instance, some such objection as "Yes, and you also said just now," and so on. For then the argument becomes to some extent personal; of the kind which will be treated of in the last section. Strictly speaking, it is half-way between the argumentum ad personam, which will there be discussed, and the argumentum ad hominem.

How very innate this trick is, may be seen in every quarrel between common people. If one of the parties makes some personal reproach against the other, the latter, instead of answering it by refuting it, allows it to stand, — as it were, admits it; and replies by reproaching his antagonist on some other ground. This is a stratagem like that pursued by Scipio when he attacked the Carthaginians, not in Italy, but in Africa. In war, diversions of this kind may be profitable; but in a quarrel they are poor expedients, because the reproaches remain, and those who look on hear the worst that can be said of both parties. It is a trick that should be used only faute de mieux.

Appeal to Authority Rather Than Reason

This is the argumentum ad verecundiam. It consists in making an appeal to authority rather than reason, and in using such an authority as may suit the degree of knowledge possessed by your opponent.

Every man prefers belief to the exercise of judgment, says Seneca; and it is therefore an easy matter if you have an authority on your side which your opponent respects. The more limited his capacity and knowledge, the greater is the number of the authorities who weigh with him. But if his capacity and knowledge are of a high order, there are very few; indeed, hardly any at all. He may, perhaps, admit the authority of professional men versed in a science or an art or a handicraft of which he knows little or nothing; but even so he will regard it with suspicion. Contrarily, ordinary folk have a deep respect for professional men of every kind. They are unaware that a man who makes a profession of a thing loves it not for the thing itself, but for the money he makes by it; or that it is rare for a man who teaches to know his subject thoroughly; for if he studies it as he ought, he has in most cases no time left in which to teach it.

But there are very many authorities who find respect with the mob, and if you have none that is quite suitable, you can take one that appears to be so; you may quote what some said in another sense or in other circumstances. Authorities which your opponent fails to understand are those of which he generally thinks the most. The unlearned entertain a peculiar respect for a Greek or a Latin flourish.

You may also, should it be necessary, not only twist your authorities, but actually falsify them, or quote something which you have invented entirely yourself. As a rule, your opponent has no books at hand, and could not use them if he had. The finest illustration of this is furnished by the French curé, who, to avoid being compelled, like other citizens, to pave the street in front of his house, quoted a saying which he described as biblical: paveant illi, ego non pavebo. That was quite enough for the municipal officers.

A universal prejudice may also be used as an authority; for most people think with Aristotle that that may be said to exist which many believe. There is no opinion, however absurd, which men will not readily embrace as soon as they can be brought to the conviction that it is generally adopted. Example affects their thought, just as it affects their action. They are like

sheep following the bell-wether just as he leads them. They would sooner die than think. It is very curious that the universality of an opinion should have so much weight with people, as their own experience might tell them that its acceptance is an entirely thoughtless and merely imitative process. But it tells them nothing of the kind, because they possess no self-knowledge whatever. It is only the elect who say with Plato tois pollois polla dokei; which means that the public has a good many bees in its bonnet, and that it would be a long business to get at them.

But to speak seriously, the universality of an opinion is no proof, nay, it is not even a probability, that the opinion is right. Those who maintain that it is so must assume (1) that length of time deprives a universal opinion of its demonstrative force, as otherwise all the old errors which were once universally held to be true would have to be recalled; for instance, the Ptolemaic system would have to be restored, or Catholicism re-established in all Protestant countries. They must assume (2) that distance of space has the same effect; otherwise the respective universality of opinion among the adherents of Buddhism, Christianity, and Islam will put them in a difficulty.

When we come to look into the matter, so-called universal opinion is the opinion of two or three persons; and we should be persuaded of this if we could see the way in which it really arises.

We should find that it is two or three persons who, in the first instance, accepted it, or advanced and maintained it; and of whom people were so good as to believe that they had thoroughly tested it. Then a few other persons, persuaded beforehand that the first were men of the requisite capacity, also accepted the opinion. These, again, were trusted by many others, whose laziness suggested to them that it was better to believe at once, than to go through the troublesome task of testing the matter for themselves. Thus the number of these lazy and credulous adherents grew from day to day; for the opinion had no sooner obtained a fair measure of support than its further supporters attributed this to the fact that the opinion could only have obtained it by the cogency of its arguments. The remainder were then compelled to grant what was universally granted, so as not to pass for unruly persons who resisted opinions which every one accepted, or pert fellows who thought themselves cleverer than any one else.

When opinion reaches this stage, adhesion becomes a duty; and henceforward the few who are capable of forming a judgment hold their peace. Those who venture to speak are such as are entirely incapable of

forming any opinions or any judgment of their own, being merely the echo of others' opinions; and, nevertheless, they defend them with all the greater zeal and intolerance. For what they hate in people who think differently is not so much the different opinions which they profess, as the presumption of wanting to form their own judgment; a presumption of which they themselves are never guilty, as they are very well aware. In short, there are very few who can think, but every man wants to have an opinion; and what remains but to take it ready-made from others, instead of forming opinions for himself?

Since this is what happens, where is the value of the opinion even of a hundred millions? It is no more established than an historical fact reported by a hundred chroniclers who can be proved to have plagiarised it from one another; the opinion in the end being traceable to a single individual. It is all what I say, what you say, and, finally, what he says; and the whole of it is nothing but a series of assertions: -

Dico ego, tu dicis, sed denique dixit et ille;
Dictaque post toties, nil nisi dicta vides.

Nevertheless, in a dispute with ordinary people, we may employ universal opinion as an authority. For it will generally be found that when two of them are fighting, that is the weapon which both of them choose as a means of attack. If a man of the better sort has to deal with them, it is most advisable for him to condescend to the use of this weapon too, and to select such authorities as will make an impression on his opponent's weak side. For, ex hypothesi, he is as insensible to all rational argument as a horny-hided Siegfried, dipped in the flood of incapacity, and unable to think or judge.

Before a tribunal the dispute is one between authorities alone, — such authoritative statements, I mean, as are laid down by legal experts; and here the exercise of judgment consists in discovering what law or authority applies to the case in question. There is, however, plenty of room for Dialectic; for should the case in question and the law not really fit each other, they can, if necessary, be twisted until they appear to do so, or vice versâ.

This is Beyond Me

If you know that you have no reply to the arguments which your opponent advances, you may, by a fine stroke of irony, declare yourself to be an incompetent judge: “What you now say passes my poor powers of comprehension; it may be all very true, but I can’t understand it, and I refrain from any expression of opinion on it”. In this way you insinuate to the bystanders, with whom you are in good repute, that what your opponent says is nonsense. Thus, when Kant’s Kritik appeared, or, rather, when it began to make a noise in the world, many professors of the old eclectic school declared that they failed to understand it, in the belief that their failure settled the business. But when the adherents of the new school proved to them that they were quite right, and had really failed to understand it, they were in a very bad humour.

This is a trick which may be used only when you are quite sure that the audience thinks much better of you than of your opponent. A professor, for instance, may try it on a student.

Strictly, it is a case of the preceding trick: it is a particularly malicious assertion of one’s own authority, instead of giving reasons. The counter-trick is to say: “I beg your pardon; but, with your penetrating intellect, it must be very easy for you to understand anything; and it can only be my poor statement of the matter that is at fault”; and then go on to rub it into him until he understands it nolens volens, and sees for himself that it was really his own fault alone. In this way you parry his attack. With the greatest politeness he wanted to insinuate that you were talking nonsense; and you, with equal courtesy, prove to him that he is a fool.

Put His Thesis Into Some Odious Category

If you are confronted with an assertion, there is a short way of getting rid of it, or, at any rate, of throwing suspicion on it, by putting it into some odious category; even though the connection is only apparent, or else of a loose character. You can say, for instance, "That is Manichaeism" or "It is Arianism," or "Pelagianism," or "Idealism," or "Spinozism," or "Pantheism," or "Brownianism," or "Naturalism," or "Atheism," or "Rationalism," "Spiritualism," "Mysticism," and so on. In making an objection of this kind, you take it for granted (1) that the assertion in question is identical with, or is at least contained in, the category cited — that is to say, you cry out, "Oh, I have heard that before"; and (2) that the system referred to has been entirely refuted, and does not contain a word of truth.

It Applies in Theory, But Not in Practice

"That's all very well in theory, but it won't do in practice." In this sophism you admit the premisses but deny the conclusion, in contradiction with a well-known rule of logic. The assertion is based upon an impossibility: what is right in theory must work in practice; and if it does not, there is a mistake in the theory; something has been overlooked and not allowed for; and, consequently, what is wrong in practice is wrong in theory too.

Don’t Let Him Off The Hook

When you state a question or an argument, and your opponent gives you no direct answer or reply, but evades it by a counter-question or an indirect answer, or some assertion which has no bearing on the matter, and, generally, tries to turn the subject, it is a sure sign that you have touched a weak spot, sometimes without knowing it. You have, as it were, reduced him to silence. You must, therefore, urge the point all the more, and not let your opponent evade it, even when you do not know where the weakness which you have hit upon really lies.

Will is More Effective Than Insight

There is another trick which, as soon as it is practicable, makes all others unnecessary. Instead of working on your opponent's intellect by argument, work on his will by motive; and he, and also the audience if they have similar interests, will at once be won over to your opinion, even though you got it out of a lunatic asylum; for, as a general rule, half an ounce of will is more effective than a hundred-weight of insight and intelligence. This, it is true, can be done only under peculiar circumstances. If you succeed in making your opponent feel that his opinion, should it prove true, will be distinctly prejudicial to his interest, he will let it drop like a hot potato, and feel that it was very imprudent to take it up.

A clergyman, for instance, is defending some philosophical dogma; you make him sensible of the fact that it is in immediate contradiction with one of the fundamental doctrines of his Church, and he abandons it.

A landed proprietor maintains that the use of machinery in agricultural operations, as practised in England, is an excellent institution, since an engine does the work of many men. You give him to understand that it will not be very long before carriages are also worked by steam, and that the value of his large stud will be greatly depreciated; and you will see what he will say.

In such cases every man feels how thoughtless it is to sanction a law unjust to himself — *quam temere in nosmet legem sancimus iniquam*! Nor is it otherwise if the bystanders, but not your opponent, belong to the same sect, guild, industry, club, etc., as yourself. Let his thesis be never so true, as soon as you hint that it is prejudicial to the common interests of the said society, all the bystanders will find that your opponent's arguments, however excellent they be, are weak and contemptible; and that yours, on the other hand, though they were random conjecture, are correct and to the point; you will have a chorus of loud approval on your side, and your opponent will be driven out of the field with ignominy. Nay, the bystanders will believe, as a rule, that they have agreed with you out of pure conviction. For what is not to our interest mostly seems absurd to us; our intellect being no siccum lumen. This trick might be called "taking the tree by its root"; its usual name is the argumentum ab utili.

Bewilder Your Opponent by Mere Bombast

You may also puzzle and bewilder your opponent by mere bombast; and the trick is possible, because a man generally supposes that there must be some meaning in words:

Gewöhnlich glaubt der Mensch, wenn er nur Worte hört,
Es müsse sich dabei doch auch was denken lassen.

If he is secretly conscious of his own weakness, and accustomed to hear much that he does not understand, and to make as though he did, you can easily impose upon him by some serious fooling that sounds very deep or learned, and deprives him of hearing, sight, and thought; and by giving out that it is the most indisputable proof of what you assert. It is a well-known fact that in recent times some philosophers have practised this trick on the whole of the public with the most brilliant success. But since present examples are odious, we may refer to The Vicar of Wakefield for an old one.

A Faulty Proof Refutes His Whole Position

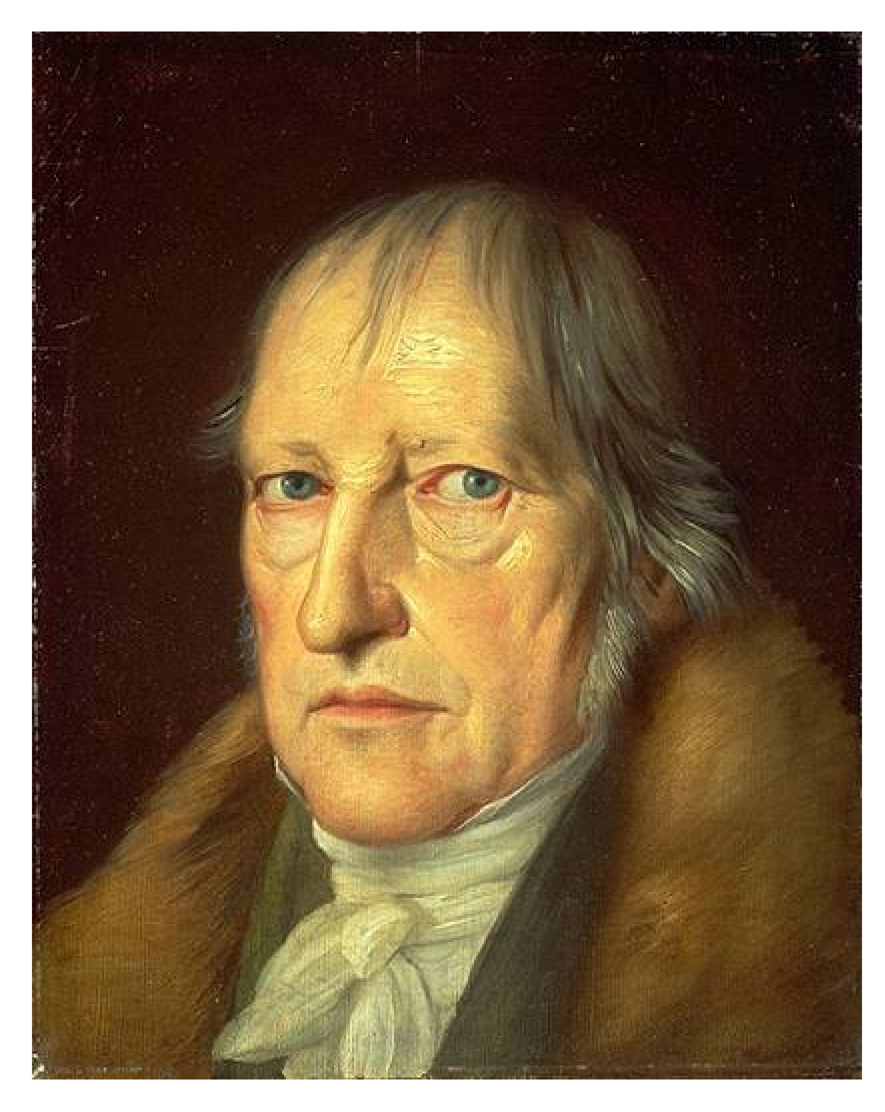
Should your opponent be in the right, but, luckily for your contention, choose a faulty proof, you can easily manage to refute it, and then claim that you have thus refuted his whole position. This is a trick which ought to be one of the first; it is, at bottom, an expedient by which an argumentum ad hominem is put forward as an argumentum ad rem. If no accurate proof occurs to him or to the bystanders, you have won the day. For example, if a man advances the ontological argument by way of proving God's existence, you can get the best of him, for the ontological argument may easily be refuted. This is the way in which bad advocates lose a good case, by trying to justify it by an authority which does not fit it, when no fitting one occurs to them.

Become Personal, Insulting, Rude

A last trick is to become personal, insulting, rude, as soon as you perceive that your opponent has the upper hand, and that you are going to come off worst. It consists in passing from the subject of dispute, as from a lost game, to the disputant himself, and in some way attacking his person. It may be called the argumentum ad personam, to distinguish it from the argumentum ad hominem, which passes from the objective discussion of the subject pure and simple to the statements or admissions which your opponent has made in regard to it. But in becoming personal you leave the subject altogether, and turn your attack to his person, by remarks of an offensive and spiteful character. It is an appeal from the virtues of the intellect to the virtues of the body, or to mere animalism. This is a very popular trick, because every one is able to carry it into effect; and so it is of frequent application. Now the question is, What counter-trick avails for the other party? for if he has recourse to the same rule, there will be blows, or a duel, or an action for slander.

ON THE WILL IN NATURE

Translated by Mme. Karl Hillebrand



During the last twenty-eight years of his life, Schopenhauer lived in Frankfurt, which he felt to be free from the threat of cholera, only leaving the city for brief interludes. He had finally renounced his career as a university professor and he lived henceforth as a recluse, wholly absorbed in his studies (particularly in the natural sciences) and his writings. His life now took on the shape that posterity first came to know: the measured uniformity of the days; the strict, ascetic lifestyle modelled after Kant; the old-fashioned attire; the tendency to gesticulative soliloquy.

His was not idle in his leisure, however. In 1836, after nineteen years of "silent indignation," he published the short treatise *On the Will in Nature*, which skilfully utilises the queries and findings of the rapidly expanding natural sciences in support of his theory of the will. The preface for the first time openly expresses the philosopher's devastating verdict on the "charlatan" Hegel and his clique.

Schopenhauer's home in Frankfurt

ON THE WILL IN NATURE

PREFACE TO THE SECOND EDITION.

To my great joy I have lived to revise even this little work, after a lapse of nineteen years, and that joy is enhanced by the special importance of this treatise for my philosophy. For, starting from the purely empirical, from the observations of unbiassed physical investigators — themselves following the clue of their own special sciences — I here immediately arrive at the very kernel of my Metaphysic; I establish its points of contact with the physical sciences and thus corroborate my fundamental dogma, in a sense, as the arithmetician proves a sum: for by this I not only confirm it more closely and specially, but even make it more clearly, easily, and rightly understood than anywhere else.

The improvements in this new edition are confined almost entirely to the Additions; for scarcely anything that is worth mentioning in the First Edition has been left out, while I have inserted many and, in some cases, important new passages.

But, even in a general sense, it may be looked upon as a good sign, that a new edition of the present treatise should have been found necessary; since it shows that there is an interest in serious philosophy and confirms the fact that the necessity for real progress in this direction is now more strongly felt than ever. This is based upon two circumstances. The first is the unparalleled zeal and activity displayed in every branch of Natural Science which, as this pursuit is mostly in the hands of people who have learned nothing else, threatens to lead to a gross, stupid Materialism, the *more immediately* offensive side of which is less the moral bestiality of its ultimate results, than the incredible absurdity of its first principles; for by it even vital force is denied, and organic Nature is degraded to a mere chance play of chemical forces.[1] These knights of the crucible and retort should be made to understand, that the mere study of Chemistry qualifies a man to become an apothecary, but not a philosopher. Certain other like-minded investigators of Nature, too, must be taught, that a man may be an accomplished zoologist and have the sixty species of monkeys at his fingers' ends, yet on the whole be an ignoramus to be classed with the vulgar, if he has learnt nothing else, save perhaps his school-catechism. But

in our time this frequently happens. Men set themselves up for enlighteners of mankind, who have studied Chemistry, or Physics, or Mineralogy and nothing else under the sun; to this they add their only knowledge of any other kind, that is to say, the little they may remember of the doctrines of the school-catechism, and when they find that these two elements will not harmonize, they straightway turn scoffers at religion and soon become shallow and absurd materialists.[2] They may perhaps have heard at college of the existence of a Plato and an Aristotle, of a Locke, and especially of a Kant; but as these folk never handled crucibles and retorts or even stuffed a monkey, they do not esteem them worthy of further acquaintance. They prefer calmly to toss out of the window the intellectual labour of two thousand years and treat the public to a philosophy concocted out of their own rich mental resources, on the basis of the catechism on the one hand, and on that of crucibles and retorts or the catalogue of monkeys on the other. They ought to be told in plain language that they are ignoramuses, who have much to learn before they can be allowed to have any voice in the matter. Everyone, in fact, who dogmatizes at random, with the *naïve* realism of a child on such arguments as God, the soul, the world's origin, atoms, &c. &c. &c., as if the Critique of Pure Reason had been written in the moon and no copy had found its way to our planet — is simply one of the vulgar. Send him into the servants' hall, where his wisdom will best find a market.[3]

The other circumstance which calls for a real progress in philosophy, is the steady growth of unbelief in the face of all the hypocritical dissembling and the outward conformity to the Church. This unbelief necessarily and unavoidably goes hand in hand with the growing expansion of empirical and historical knowledge. It threatens to destroy not only the form, but even the spirit of Christianity (a spirit which has a much wider reach than Christianity itself), and to deliver up mankind to *moral* materialism — a thing even more dangerous than the chemical materialism already mentioned. And nothing plays more into the hands of this unbelief, than the Tartuffianism *de rigueur* impudently flaunting itself everywhere just now, whose clumsy disciples, fee in hand, hold forth with such unction and emphasis, that their voices penetrate even into learned, critical reviews issued by Academies and Universities, and into physiological as well as philosophical books, where however, being quite in their wrong place, they only damage their own cause by rousing indignation.[4] Under such

circumstances as these, it is gratifying to see the public betray an interest in philosophy.

I have nevertheless one sad piece of news to communicate to our professors of philosophy. Their Caspar Hauser (according to Dorguth) whom they had so carefully secreted, so securely walled up for nearly forty years, that no sound could betray his existence to the world — their Caspar Hauser — I say, has escaped! He has escaped and is running about in the world; — some even say he is a prince. In plain language, the misfortune they feared more than anything has come to pass after all. In spite of their having done their best to prevent it for more than a generation by acting with united force, with rare constancy, secreting and ignoring to a degree that is without example, my books are beginning and henceforth will continue to be read. *Legor et legar*: there is no help for it. This is really dreadful and most inopportune; nay, it is a positive fatality, not to say calamity. Is this the recompense for all their faithful, snug secrecy; for having held so firmly and unitedly together? Poor time-servers! What becomes of Horace's assurance: —

"Est et fideli tuta silentio
Merces, —— ?"

For verily they have not been deficient in faithful reticence; rather do they excel in this quality wherever they scent merit. And, after all, it is no doubt the cleverest artifice; for what no one knows, is as though it did not exist. Whether the *merces* will remain quite so *tuta*, seems rather doubtful — unless we are to take *merces* in a *bad* sense; and for this the support of many a classical authority might certainly be found. These gentlemen had seen quite rightly that the only means to be used against my writings, was to secrete them from the public by maintaining profound silence concerning them, while they kept up a loud noise at the birth of every misshapen offspring of professorial philosophy; as the voice of the new-born Zeus was drowned in days of yore by the clashing of the cymbals of the Corybantes. But this expedient is now used up; the secret is out — the public has discovered me. The rage of our professors of philosophy at this is great, but powerless; for their only effective resource, so long successfully employed, being exhausted, no snarling can avail any longer against my influence, and in vain do they now take this, or that, or the other attitude. They have certainly succeeded, so far as the generation which was properly speaking contemporaneous with my philosophy, went to the grave in ignorance of it.

But this was a mere postponement, and Time has kept its word, as it always does.

Now there are two reasons why these gentlemen "in the philosophical trade" — as they call themselves with incredible *naïveté* — hate my philosophy. The first of them is, that my writings spoil the taste of the public for tissues of empty phrases, for accumulations of unmeaning words piled one upon another, for hollow, superficial, brain-racking twaddle, for Christian dogmatics under the disguise of the most wearisome Metaphysics, for systematized Philistinism of the flattest kind made to represent Ethics and even accompanied by instructions for card-playing and dancing — in short, they unfit my readers for the whole method of philosophising *à la vieille femme*, which has scared so many for ever from the pursuit of philosophy.

The second reason is, that our gentlemen "in the trade" are absolutely bound in conscience not to let my philosophy pass and are therefore debarred from using it for the benefit of "the trade;" — and this they even heartily regret; for my abundance might have been admirably turned to account for the benefit of their own needy poverty. But even if it contained the greatest hoards of human wisdom ever unearthed, my doctrine could never find favour with them either now or in the future; for it is absolutely wanting in all Speculative Theology and Rational Psychology, and these, just these, are the very breath of life to these gentlemen, the *sine qua non* of their existence. For they are anxious before all things in heaven and on earth, to hold their official appointments, and these appointments demand before all things in heaven and on earth a Speculative Theology and a Rational Psychology: *extra hæc non datur salus*. Theology there must and shall be, no matter whence it come; Moses and the Prophets must be made out to be in the right: this is the highest principle in philosophy; and there must be Rational Psychology to boot, as is proper. Now there is nothing of the sort to be found either in Kant's philosophy or in mine. For, as we all know, the most cogent theological argumentation shivers to atoms like a glass thrown at a wall, when it is brought into contact with Kant's Critique of all Speculative Theology, and under his hands not a shred remains entire of the whole tissue of Rational Psychology! As to myself, being the bold continuer of Kant's philosophy, I have entirely done away with all Speculative Theology and all Rational Psychology, as is only consistent and honest.[5] On the other hand, the task incumbent upon University Philosophy

is at bottom this: to set forth the chief fundamental truths belonging to the Catechism under the veil of some very abstract, abstruse and difficult, therefore painfully wearisome formulas and sentences; wherefore, however confused, intricate, strange and eccentric the matter may seem at first sight, these truths invariably reveal themselves as its kernel. This proceeding may be useful, though to me it is unknown. All I know is, that philosophy, *i.e.* the search after truth — I mean the truth κατ' ἐξοχήν, by which the most sublime and important disclosures, more precious than anything else to the human race, are understood — will never advance a step, nay, an inch, by means of such manœuvring, by which its course is on the contrary impeded; therefore I found out long ago that University philosophy is the enemy of all genuine philosophy. Now, this being the state of the case, when a really honest philosophy arises, which seriously has truth for its sole aim, must not these gentlemen "of the philosophical trade" feel as might stage-knights in paste-board armour, were a knight suddenly to appear in the midst of them clad in real armour, who made the stage-floor creak under his ponderous tread? Such philosophy as this *must* therefore be bad and false and consequently places these gentlemen "of the trade" under the painful obligation of playing the part of him who, in order to appear what he is not, cannot allow others to pass for what they really are. Out of all this however there unrolls itself the amusing spectacle we enjoy, when these gentlemen, now that ignoring has unfortunately come to an end, after forty years, at last begin to measure me by their own puny standard and pass judgment upon me from the heights of their wisdom, as though they were amply qualified to do so by their office; but they are most amusing of all when they assume airs of superiority towards me.

Their abhorrence of Kant, though less openly expressed, is scarcely less great than their hatred of me; precisely because all speculative Theology and all Rational Psychology — the bread-winners of these gentlemen — have been undermined, not to say irrevocably ruined, by him in the eyes of all serious thinkers. What! Not hate him? him, who has made their "trade in philosophy" so difficult to them, that they hardly see how to pull through honourably! So Kant and I are accordingly both bad, and these gentlemen quite overlook us. For nearly forty years they have not deigned to cast a glance upon me, and now they look down condescendingly upon Kant from the heights of their wisdom, smiling in pity at his errors. This policy is both very wise and very profitable; since they are thus able to hold forth at their

ease volume after volume upon God and the soul, as if these were personalities with whom they were intimately acquainted, and to discourse upon the relation in which the former stands to the world and the latter to the body, just as if there had never been such a thing as a Critique of Pure Reason. When once the Critique of Pure Reason is done away with, all will go on splendidly! Now it is for this end that they have been endeavouring for many years quietly and gradually to set Kant aside, to make him obsolete, nay, to turn up their noses at him, and one being encouraged by the other in this, they are becoming bolder every day.[6] They have no opposition to fear from their own colleagues, since they all have the same aims and the same mission and all together form a numerous *coterie*, the brilliant members of which, *coram populo*, bow and scrape to each other on all sides. Thus by degrees things have come to such a point, that the wretchedest compilers of manuals have the presumption to treat Kant's grand, immortal discoveries as antiquated errors, nay, calmly to set them aside with the most ludicrous arrogance and most impudent dicta of their own, which they nevertheless lay down under the disguise of argumentation, because they know they may count upon a credulous public, to whom Kant's writings are not known.[7] And this is what happens to Kant on the part of writers, whose total incapacity strikes us in every page, not to say every line, we read of their unmeaning, stupefying verbiage! Were this to go on much longer, Kant would present the spectacle of the dead lion being kicked by the donkey. Even in France there is no lack of fellow-workers inspired by a similar orthodoxy, who are labouring towards the same end. A certain M. Barthélemy de St. Hilaire, for instance, in a lecture delivered in the *Académie des Sciences Morales* in April, 1850, has presumed to criticize Kant with an air of condescension and to use most improper language in speaking of him; luckily however in such a way, that no one could fail to see the underlying purpose.[8]

Now others among our German "traders in philosophy" again try to get rid of the obnoxious Kant in a different way: instead of attacking his philosophy point-blank, they rather seek to undermine the foundations on which it is built. These people however are so utterly forsaken by all the gods and by all power of judgment, that they attack *à priori* truths: that is to say, truths as old as the human understanding, nay, which constitute that understanding itself, and which it is therefore impossible to contradict without declaring war against that understanding also. So great however is

the courage of these gentlemen. I am sorry to say I know of three,[9] and I am afraid there are a good many more at work at this undermining process, who have the incredible presumption to maintain the *à posteriori* origin of Space as a consequence, a mere relation, of the objects *within it*; for they assert that Space and Time are of empirical origin and attached to those bodies, so that [according to them] Space first arises through our perception of the juxtaposition of bodies and Time likewise through our perception of the succession of changes (*sancta simplicitas!* as if the words "collateral" and "successive" would have any sense for us without the antecedent intuitions of Space and of Time to give them a meaning); consequently, that if there were no bodies, there would be no Space, therefore if they disappeared Space also must lapse, and that if all changes were to stop, Time also would stop.[10]

And such stuff as this is gravely taught fifty years after Kant's death! The aim of it is, as we know, to undermine Kantian philosophy, and certainly if these propositions were true, *one* stroke would suffice to overthrow it. Fortunately however these assertions are of a kind which is met by derision rather than by serious refutation. For, in them, the question is one of heresy, not so much against Kantian philosophy, as against common sense; and they are not so much an attack upon any particular philosophical dogma, as upon an *à priori* truth which, as such, constitutes human understanding itself, and therefore must be instantaneously evident to every one who is in his senses, just as much as that 2 × 2 = 4. Fetch me a peasant from the plough; make the question intelligible to him; and he will tell you, that even if all things in Heaven and on Earth were to vanish, Space would nevertheless remain, and that if all changes in Heaven and on Earth were to cease, Time would nevertheless flow on. Compared with German pseudo-philosophers like these, how estimable does a man like the French physicist Pouillet appear, who, though he never troubles his head about Metaphysics, is careful to incorporate two long paragraphs, one on *l'Espace*, the other on *le Temps*, in the first chapter of his well-known Manual, on which public instruction in France is based, where he shows that if all Matter were annihilated, Space would still remain, and that Space is infinite; and that if all changes ceased, Time would still pursue its course without end. Now here he does not appeal, as in all other cases, to experience, because in this case experience is not possible; yet he speaks with apodeictic certainty. For, as a physicist, professing a science which is

absolutely immanent — *i.e.* limited to the reality that is empirically given — it never comes into his head to inquire whence he knows all this. It *did* come into Kant's head, and it was this very problem, clothed by him in the severe form of an inquiry as to the possibility of synthetical *à priori* judgments, that became the starting-point and the corner-stone of his immortal discoveries, or in other words, of Transcendental Philosophy which, precisely by answering this question and others related to it, shows what is the nature of that empirical reality itself.[11]

And seventy years after the Critique of Pure Reason had appeared and filled the world with its fame, these gentlemen dare to serve up such gross absurdities, which were done away with long ago, and to return to former barbarism. If Kant were to come back and see all this mischief, he would feel like Moses on returning from Mount Sinai, when he found his people worshipping the golden calf, and dashed the Tables to pieces in his anger. But if Kant were to take things as tragically as Moses, I should console him with the words of Jesus Sirach:[12] "He that telleth a tale to a fool speaketh to one in a slumber; when he hath told his tale, he will say, 'What is the matter?'" For that diamond in Kant's crown, Transcendental Æsthetic, never has existed for these gentlemen — it is tacitly set aside, as *non-avenue*. I wonder what they think Nature means by producing the rarest of all her works, a great mind, one among so many hundreds of millions, if the worshipful company of numskulls are to be able at their pleasure and by their mere counter-assertion to annul the weightiest doctrines emanating from that mind, let alone to treat them with disregard and do as if they did not exist.

But this degenerate, barbarous state of philosophy which, in the present day, emboldens every tyro to hold forth at random upon subjects that have puzzled the greatest minds, is precisely a consequence still remaining of the impunity with which — thanks to the connivance of our professors of philosophy — that audacious scribbler, Hegel, has been allowed to flood the market with his monstrous vagaries and so to pass for the greatest of all philosophers for the last thirty years in Germany. Every one of course now thinks himself entitled to serve up confidently anything that may happen to come into his sparrow's brain.

Therefore, as I have said, the gentlemen of the 'philosophical trade' are anxious before all things to obliterate Kant's philosophy, in order to be able to return to the muddy canal of the old dogmatism and to talk at random to

their heart's content upon the favourite subjects which are specially recommended to them: just as if nothing had happened and neither a Kant nor a Critical Philosophy had ever come into the world.[13] The affected veneration for, and laudation of, Leibnitz too, which has been showing itself everywhere for some years, proceed from the same source. They like to place him in a line with, nay above, Kant, having at times the assurance to call him the greatest of all German philosophers. Now, compared with Kant, Leibnitz is a poor rushlight. Kant is a master-mind, to whom mankind is indebted for the discovery of never-to-be-forgotten truths. One of his chief merits is precisely, to have delivered us from Leibnitz and his subtleties: from pre-established harmonies, monads and *identitas indiscernibilium*. Kant has made philosophy serious and I am keeping it so. That these gentlemen should think differently is easily explained; for has not Leibnitz a central Monad and a *Theodicée* also, with which to deck it out? Now this is quite to the taste of my gentlemen 'of the philosophical trade.' It does not stand in the way of earning a honest livelihood; it allows one to subsist; whereas such a thing as Kant's "Critique of all Speculative Theology," makes one's hair stand on end. Kant is consequently a wrong-headed man and one to be set aside. Vivat Leibnitz! Vivat the 'philosophical trade!' Vivat old woman's philosophy! These gentlemen really imagine that, according to the standard of their own petty aims, they can obscure what is good, disparage what is great, and accredit what is false. They may perhaps succeed in doing so for a time, but certainly not in the long run, nor with impunity. Notwithstanding all their machinations and spiteful ignoring of me for forty years, have not even I at last made my way? During those forty years however I have learnt to appreciate Chamfort's words: "*En examinant la ligue des sots contre les gens d'esprit, on croirait voir une conspiration de valets pour écarter les maîtres.*"

We do not care to have much to do with those whom we dislike. One of the consequences of this antipathy for Kant, therefore, has been an incredible ignorance of his doctrines. I can scarcely believe my eyes at times, when I see certain proofs of this ignorance, and must here support my assertion by a few examples. First let me present a very singular specimen, though it is now some years old. In Professor Michelet's "Anthropology and Psychology" (p. 444), he states Kant's Categorical Imperative in the following words: "thou must, for thou canst" (*du sollst, denn du kannst*). This cannot be a *lapsus calami*, for he again states it in the

same words in his "History of the Development of Modern German Philosophy" (p. 38),[14] published three years later. Letting alone the fact that he appears to have studied Kantian philosophy in Schiller's epigrams, he has thus turned the thing upside down, and expressed exactly the opposite of Kant's argument; evidently without having the slightest inkling of what Kant meant by that postulate of Freedom on the basis of his Categorical Imperative. None of Professor Michelet's colleagues, to my knowledge, have pointed out this mistake, but "*hanc veniam damus, petimusque vicissim*." — Another more recent instance. The above mentioned reviewer of Oersted's book (see note 1 (*c*), p. 202), to whose title the present treatise unfortunately had to stand godfather, comes in that work on the sentence that "bodies are spaces filled with force" (*krafterfüllte Räume*). This is new to him; so without the faintest suspicion that he has to do with a far-famed Kantian dogma, and taking this for a paradoxical opinion of Oersted's, he attacks it and argues against it bravely, persistently and repeatedly in both his reviews, which appeared at an interval of three years from one another, using arguments like these: "Force cannot fill Space without something substantial, Matter;" then again three years later: "Force in Space does not yet constitute any thing. For Force to fill Space, there must be Substance, Matter. A mere force can never fill. Matter must be there for it to fill." — Bravo! my cobbler would use just such arguments as these.[15] — When I see *specimina eruditionis* of this sort, I begin to have my misgivings whether I did not do the man injustice by naming him among those who endeavour to undermine Kant; but in this, to be sure, I had in view his assertions that "Space is but the relation, the juxtaposition of things,"[16] and that "Space is a relation in which things stand, a juxtaposition of things. This juxtaposition ceases to be a conception as soon as the conception of Matter ceases."[17] For he might possibly have penned these sentences in sheer innocence, since he may have known no more of the "Transcendental Æsthetic" than of the "Metaphysical First Principles of Natural Science;" though to be sure, this would be rather extraordinary for a professor of philosophy. Now-a-days however we must not be surprised at anything. For all knowledge of Critical Philosophy has died out, in spite of its being the latest true philosophy that has appeared, and a doctrine withal, that has made a revolution and epoch in human knowledge and thought. Now therefore, since it has overthrown all previous systems, and since the knowledge of it has died out, philosophising no longer proceeds on the basis of any of the doctrines

propounded by the great minds of the past, but becomes a mere random untutored process, having an ordinary education and the catechism for its foundation. Now that I have startled them however, our professors may perhaps take to studying Kant's works again. Still Lichtenberg says: "Past a certain age, I think it as impossible to learn Kantian Philosophy as to learn rope-dancing."

I should certainly not have condescended to record the sins of these sinners had not the interests of truth required that I should do so, in order to show the state of degradation at which German Philosophy has arrived fifty years after Kant's death in consequence of the machinations of the gentlemen 'of the trade,' and also to show what would result, if these puny minds, who know nothing but their own ends, were to be suffered without hindrance to check the influence of the great geniuses who have illumined the world. I cannot look on at this in silence; it is rather a case to which Göthe's exhortation applies:

"Du Kräftiger, sei nicht so still,
Wenn auch sich Andre scheuen:
Wer den Teufel erschrecken will,
Der muss laut schreien."

Dr. Martin Luther thought so also.

Hatred against Kant, hatred against me, hatred against truth, all however *in majorem Dei gloriam*, is what inspires these worthies who live on philosophy. Who can be so blind as not to see that University philosophy is the enemy of all true, serious philosophy, whose progress it feels bound to withstand? For a philosophy which deserves the name, is pure service of truth, therefore the most sublime of all human endeavours; but, as such, it is not adapted for a trade. Least of all can it have its seat in Universities, where a theological Faculty predominates and things are irrevocably decided beforehand ere philosophy comes to them. With Scholasticism, from which University philosophy descends, it was quite a different thing. Scholasticism was avowedly the *ancilla theologiæ*, so that here the name corresponded to the thing. Our University philosophy of to-day, on the contrary, disclaims the connection, and professes independent research; yet in reality it is only the *ancilla* disguised, and it is intended no less than its predecessor to be the servant of Theology. Thus genuine, sincerely meant philosophy has an adversary under the guise of an ally in University philosophy. Therefore I said long ago, that nothing would be of greater

benefit to philosophy than for it to cease altogether to be taught at Universities; and if at that time I still admitted the propriety of a brief, quite succinct course of History of Philosophy accompanying Logic — which undoubtedly ought to be taught at Universities — I have since withdrawn that hasty concession in consequence of the following disclosure made to us in the *Göttingischen Gelehrten Anzeigen* of the 1st January, 1853, p. 8, by the *Ordinarius loci* (one who writes History of Philosophy in thick volumes): "It could not be mistaken that Kant's doctrine is ordinary Theism, and that it has contributed little or nothing towards transforming the current views on God and his relation to the world." — If this is the state of the case, Universities are in my opinion no longer the right place even for teaching History of Philosophy. There designs and intentions reign paramount. I had indeed long ago begun to suspect, that History of Philosophy was taught at our Universities in the same spirit and with the same *granum salis* as Philosophy itself, and it needed but very little to make my suspicions certainty. Accordingly it is my wish to see both Philosophy and its History disappear from the lecture-list, because I desire to rescue them from the tender mercies of our court-councillors.[18] But far be it from me, to wish to see our professors of philosophy removed from their thriving business at our Universities. On the contrary, what I should like would be, to see them promoted three degrees higher in dignity and raised to the highest faculty, as professors of Theology. For at the bottom they have really been this for some time already, and have served quite long enough as volunteers.

Meanwhile my honest and kindly advice to the young generation is, not to waste any time with University philosophy, but to study Kant's works and my own instead. I promise them that there they will learn something substantial, that will bring light and order into their brains: so far at least as they may be capable of receiving them. It is not good to crowd round a wretched farthing rushlight when brilliant torches are close by; still less to run after will o' the wisps. Above all, my truth-seeking young friends, beware of letting our professors tell you what is contained in the Critique of Pure Reason. Read it yourselves, and you will find in it something very different from what they deem it advisable for you to know. — In our time a great deal too much study is generally devoted to the History of Philosophy; for this study, being adapted by its very nature to substitute knowledge for reflection, is just now cultivated downright with a view to making

philosophy consist in its own history. It is not only of doubtful necessity, but even of questionable profit, to acquire a superficial half-knowledge of the opinions and systems of all the philosophers who have taught for 2,500 years; yet what more does the most honest history of philosophy give? A real knowledge of philosophers can only be acquired from their own works, and not from the distorted image of their doctrines as it is found in the commonplace head.[19] But it is really urgent that order should be brought into our heads by some sort of philosophy, and that we should at the same time learn to look at the world with a really unbiassed eye. Now no philosophy is so near to us, both as regards time and language, as that of Kant, and it is at the same time a philosophy, compared with which all those which went before are superficial. On this account it is unhesitatingly to be preferred to all others.

But I perceive that the news of Caspar Hauser's escape has already spread among our professors of philosophy; for I see that some of them have already given vent to their feelings in bitter and venomous abuse of me in various periodicals, making up by falsehoods for their deficiency of wit.[20] Nevertheless I do not complain of all this, because I am rejoiced at the cause and amused by the effect of it, as illustrative of Göthe's verse:

"Es will der Spitz aus unserm Stall
Uns immerfort begleiten:
Doch seines Bellens lauter Schall
Beweist nur, dass wir reiten."

Arthur Schopenhauer.

Frankfurt am Mein,
August, 1854.

EDITOR'S PREFACE TO THE THIRD EDITION.

Schopenhauer has left an interleaved copy of his work "On the Will in Nature," as well as of his other writings, and has inserted in it those Corrections and Additions which he intended to use for the Third Edition. I have therefore included them in this Third Edition.

The Corrections chiefly concern the style, here and there an expression being changed, and a word inserted or omitted. The Additions, on the contrary, concern the *matter* of the book; they amplify it more or less considerably, and are tolerably numerous.

The Corrections are incorporated by Schopenhauer with the text; whereas the Additions are designated by him as "Notes" (*Anmerkungen*) to be placed at the foot of the pages with the words, "added to the third edition." They will therefore be found at the places indicated by him for them, as foot-notes; and thus the reader will be enabled easily to discern how much has been added in this edition.

As to the value of the present work, Schopenhauer has expressed himself as follows in the "World as Will and Representation:"

"It would be a great mistake to consider the foreign deliverances with which I have connected my own exposition there (in the work "On the Will in Nature") as the real substance and argument of that work which, though small in size, is weighty in import. They are rather a mere occasion which I take as my starting-point in order to expound the fundamental truth of my doctrine more clearly there than has been done anywhere else, and to apply it all the way down even to the empirical knowledge of Nature. This I have done most exhaustively and stringently under the heading "Physical Astronomy," nor can I ever hope to find a more correct or accurate expression for the kernel of my doctrine than the one given there."[21]

I have nothing to add to testimony thus given by Schopenhauer himself.

Julius Frauenstädt.

Berlin, *March, 1867*.

EDITOR'S PREFACE TO THE FOURTH EDITION.

The present Fourth Edition is an identical reprint of the Third: it therefore contains the same Corrections and Additions which I had already inserted in the Third Edition from Schopenhauer's own manuscript.

Julius Frauenstädt.

Berlin, *September, 1877*.

INTRODUCTION.

I break silence after seventeen years,[22] in order to point out to the few who, in advance of the age, may have given their attention to my philosophy, sundry corroborations which have been contributed to it by unbiassed empiricists, unacquainted with my writings, who, in pursuing their own road in search of merely empirical knowledge, discovered at its extreme end what my doctrine has propounded as the Metaphysical (*das Metaphysische*), from which the explanation of experience as a whole must come. This circumstance is the more encouraging, as it confers upon my system a distinction over all hitherto existing ones; for all the other systems, even the latest — that of Kant — still leave a wide gap between their results and experience, and are far from coming down directly to, and into contact with, experience. By this my Metaphysic proves itself to be the only one having an extreme point in common with the physical sciences: a point up to which these sciences come to meet it by their own paths, so as really to connect themselves and to harmonize with it. Moreover this is not brought about by twisting and straining the empirical sciences in order to adapt them to Metaphysic, nor by Metaphysic having been secretly abstracted from them beforehand and then, *à la* Schelling, finding *à priori* what it had learnt *à posteriori*. On the contrary, both meet at the same point of their own accord, yet without collusion. My system therefore, far from soaring above all reality and all experience, descends to the firm ground of actuality, where its lessons are continued by the Physical Sciences.

Now the extraneous and empirical corroborations I am about to bring forward, all concern the kernel and chief point of my doctrine, its Metaphysic proper. They concern, that is, the paradoxical fundamental truth,

that what Kant opposed as *thing in itself* to mere *phenomenon* — called more decidedly by me *representation* — and what he held to be absolutely unknowable, that this *thing in itself*, this substratum of all phenomena, and therefore of the whole of Nature, is nothing but what we know directly and intimately and find within ourselves as *the will*;[23]

that accordingly, this *will*, far from being inseparable from, and even a mere result of, *knowledge*, differs radically and entirely from, and is quite independent of, knowledge, which is secondary and of later origin; and can

consequently subsist and manifest itself without knowledge: a thing which actually takes place throughout the whole of Nature, from the animal kingdom downwards;

that this *will*, being the one and only thing in itself, the sole truly real, primary, metaphysical thing in a world in which everything else is only phenomenon — *i.e.* mere representation — gives all things, whatever they may be, the power to exist and to act;

that accordingly, not only the voluntary actions of animals, but the organic mechanism, nay even the shape and quality of their living body, the vegetation of plants and finally, even in inorganic Nature, crystallization, and in general every primary force which manifests itself in physical and chemical phenomena, not excepting Gravity, — that all this, I say, in itself, *i.e.* independently of phenomenon (which only means, independently of our brain and its representations), is absolutely identical with the *will* we find within us and know as intimately as we can know anything;

that further, the individual manifestations of the will are set in motion by *motives* in beings gifted with an intellect, but no less by *stimuli* in the organic life of animals and of plants, and finally in all inorganic Nature, by *causes* in the narrowest sense of the word — these distinctions applying exclusively to phenomena;

that, on the other hand, knowledge with its substratum, the intellect, is a merely secondary phenomenon, differing completely from the will, only accompanying its higher degrees of objectification and not essential to it; which, as it depends upon the manifestations of the will in the animal organism, is therefore physical, and not, like the will, metaphysical;

that we are never able therefore to infer absence of will from absence of knowledge; for the will may be pointed out even in all phenomena of unconscious Nature, whether in plants or in inorganic bodies; in short,

that the will is not conditioned by knowledge, as has hitherto been universally assumed, although knowledge *is* conditioned by the will.

Now this fundamental truth, which even to-day sounds so like a paradox, is the part of my doctrine to which, in all its chief points, the empirical sciences — themselves ever eager to steer clear of all Metaphysic — have contributed just as many confirmations forcibly elicited by the irresistible cogency of truth, but which are most surprising on account of the quarter whence they proceed; and although they have certainly come to light since the publication of my chief work, it has been quite independently of it and

as the years went on. Now, that it should be precisely this fundamental doctrine of mine which has thus met with confirmation, is advantageous in two respects. First, because it is the main thought upon which my system is founded; secondly, because it is the only part of my philosophy that admits of confirmation through sciences which are alien to, and independent of, it. For although the last seventeen years, during which I have been constantly occupied with this subject, have, it is true, brought me many corroborations as to other parts, such as Ethics, Æsthetics, Dianoiology; still these, by their very nature, pass at once from the sphere of actuality, whence they arise, to that of philosophy itself: so they cannot claim to be extraneous evidence, nor can they, as collected by me, have the same irrefragable, unequivocal cogency as those concerning *Metaphysics* proper which are given by its correlate *Physics* (in the wide sense of the word which the Ancients gave it). For, in pursuing its own road, Physics, *i.e.*, Natural Science as a whole, must in all its branches finally come to a point where physical explanation ceases. Now this is precisely the *Metaphysical*, which Natural Science only apprehends as the impassable barrier at which it stops short and henceforth abandons its subject to Metaphysics. Kant therefore was quite right in saying: "It is evident, that the primary sources of Nature's agency must absolutely belong to the sphere of Metaphysics."[24] Physical science is wont to designate this unknown, inaccessible something, at which its investigations stop short and which is taken for granted in all its explanations, by such terms as physical force, vital force, formative principle, &c. &c., which in fact mean no more than *x, y, z*. Now if nevertheless, in single, propitious instances, specially acute and observant investigators succeed in casting as it were a furtive glance behind the curtain which bounds off the domain of Natural Science, and are able not only to feel it is a barrier but, in a sense, to obtain a view of its nature and thus to peep into the metaphysical region beyond; if moreover, having acquired this privilege, they explicitly designate the limit thus explored downright as that which is stated to be the true inner essence and final principle of all things by a system of Metaphysics unknown to them, which takes its reasons from a totally different sphere and, in every other respect, recognises all things merely as phenomena, *i.e.*, as representation — then indeed the two bodies of investigators must feel like two mining engineers driving a gallery, who, having started from two points far apart and worked for some time in subterranean darkness, trusting exclusively to compass and

spirit-level, suddenly to their great joy catch the sound of each other's hammers. For now indeed these investigators know, that the point so long vainly sought for has at last been reached at which Metaphysics and Physics meet — they, who were as hard to bring together as Heaven and Earth — that a reconciliation has been initiated and a connection found between these two sciences. But the philosophical system which has witnessed this triumph receives by it the strongest and most satisfactory proof possible of its own truth and accuracy. Compared with such a confirmation as this, which may, in fact, be looked upon as equivalent to proving a sum in arithmetic, the regard or disregard of a given period of time loses all importance, especially when we consider what has been the subject of interest meanwhile and find it to be — the sort of philosophy we have been treated to since Kant. The eyes of the public are gradually opening to the mystification by which it has been duped for the last forty years under the name of philosophy, and this will be more and more the case. The day of reckoning is at hand, when it will see whether all this endless scribbling and quibbling since Kant has brought to light a single truth of any kind. I may thus be dispensed from the obligation of entering here into subjects so unworthy; the more so, as I can accomplish my purpose more briefly and agreeably by narrating the following anecdote. During the carnival, Dante having lost himself in a crowd of masks, the Duke of Medici ordered him to be sought for. Those commissioned to look for him, being doubtful whether they would be able to find him, as he was himself masked, the Duke gave them a question to put to every mask they might meet who resembled Dante. It was this: "Who knows what is good?" After receiving several foolish answers, they finally met with a mask who replied: "He that knows what is bad," by which Dante was immediately recognised.[25] What is meant by this here is, that I have seen no reason to be disheartened on account of the want of sympathy of my contemporaries, since I had at the same time before my eyes the objects of their sympathy. What those authors were, posterity will see by their works; what the contemporaries were, will be seen by the reception they gave to those works. My doctrine lays no claim whatever to the name "Philosophy of the present time" which was disputed to the amusing adepts of Hegel's mystification; but it certainly does claim the title of "Philosophy of time to come:" that is, of a time when people will no longer content themselves with a mere jingle of words without meaning, with empty phrases and trivial parallelisms, but will exact real contents and

serious disclosures from philosophy, while, on the other hand, they will exempt it from the unjust and preposterous obligation of paraphrasing the national religion for the time being. “For it is an extremely absurd thing,” says Kant,[26] “to expect to be enlightened by Reason and yet to prescribe to her beforehand on which side she must incline.” — It is indeed sad to live in an age so degenerate, that it should be necessary to appeal to the authority of a great man to attest so obvious a truth. But it is absurd to expect marvels from a philosophy that is chained up, and particularly amusing to watch the solemn gravity with which it sets to work to accomplish great things, when we all know beforehand “the short meaning of the long speech.”[27] However the keen-sighted assert that under the cloak of philosophy they can mostly detect theology holding forth for the edification of students thirsting after truth, and instructing them after its own fashion; — and this again reminds us forcibly of a certain favourite scene in Faust. Others, who think that they see still further into the matter, maintain that what is thus disguised is neither theology nor philosophy, but simply a poor devil who, while solemnly protesting that he has lofty, sublime truth for his aim, is in fact only striving to get bread for himself and for his future young family. This he might no doubt obtain by other means with less labour and more dignity; meanwhile however for this price he is ready to do anything he is asked to do, even to deduce *à priori*, nay, should it come to the worst, to perceive, the ‘Devil and his dam,’ by intellectual intuition — and here indeed the exceedingly comical effect is brought to a climax by the contrast between the sublimity of the ostensible, and the lowliness of the real, aim. It remains nevertheless desirable, that the pure, sacred precincts of philosophy should be cleansed of all such traders, as was the temple of Jerusalem in former times of the buyers and sellers. — Biding such better times therefore, may our philosophical public bestow its attention and interest as it has done hitherto. May it continue as before invariably naming Fichte as an obligato accompaniment to, and in the same breath with, Kant — that great mind, produced but once by Nature, which has illumined its own depth — as if forsooth they were of the same kind; and this without a single voice being heard to exclaim in protest Ἡρακλῆς καὶ πίθηκος! May Hegel’s philosophy of absolute nonsense — three-fourths cash and one-fourth crazy fancies — continue to pass for unfathomable wisdom without anyone suggesting as an appropriate motto for his writings Shakespeare’s words: “Such stuff as madmen tongue and brain not,” or, as

an emblematical vignette, the cuttle-fish with its ink-bag, creating a cloud of darkness around it to prevent people from seeing what it is, with the device: *mea caligine tutus*. — May each day bring us, as hitherto, new systems adapted for University purposes, entirely made up of words and phrases and in a learned jargon besides, which allows people to talk whole days without saying anything; and may these delights never be disturbed by the Arabian proverb: “I hear the clappering of the mill, but I see no flour.” — For all this is in accordance with the age and must have its course. In all times some such thing occupies the contemporary public more or less noisily; then it dies off so completely, vanishes so entirely, without leaving a trace behind, that the next generation no longer knows what it was. Truth can bide its time, for it has a long life before it. Whatever is genuine and seriously meant, is always slow to make its way and certainly attains its end almost miraculously; for on its first appearance it as a rule meets with a cool, if not ungracious, reception: and this for exactly the same reason that, when once it is fully recognised and has passed on to posterity, the immense majority of men take it on credit, in order to avoid compromising themselves, whereas the number of genuine appreciators remains nearly as small as it was at first. These few nevertheless suffice to make the truth respected, for they are themselves respected. And thus it is passed from hand to hand through centuries over the heads of the inept multitude: so hard is the existence of mankind’s best inheritance! — On the other hand, if truth had to crave permission to be true from such as have quite different aims at heart, its cause might indeed be given up for lost; for then it might often be dismissed with the witches’ watch-word: “fair is foul, and foul is fair.” Luckily however this is not the case. Truth depends upon no one’s favour or disfavour, nor does it ask anyone’s leave: it stands upon its own feet, and has Time for its ally; its power is irresistible, its life indestructible.

PHYSIOLOGY AND PATHOLOGY.

In classifying the above-mentioned empirical corroborations of my doctrine according to the sciences from which they come, while I take the graduated order of Nature from the highest to the lowest degree as a guiding-thread to my expositions, I must first mention a very striking confirmation lately received by my chief dogma in the physiological and pathological views of Dr. J. D. Brandis, private physician to the King of Denmark, a veteran in science, whose "Essay on Vital Force" (1795) had received Reil's hearty commendation. In his two latest writings: "Experiences in the Application of Cold in Disease" (Berlin, 1833), and "Nosology and Therapeutics of Cachexiæ" (1834), we find him in the most emphatic and striking manner stating the primary source of all vital functions to be an *unconscious will*, from which he derives all processes in the machinery of the organism, in health as well as in disease, and which he represents as the *primum mobile* of life. I must support this by literal quotations from these essays, since few save medical readers are likely to have them at hand.

In the first of them, p. viii., we find: "The essence of every living organism consists in the will to maintain its own existence as much as possible over against the macrocosm;" — p. x.: "Only *one* living entity, *one* will can be in an organ at the same time; therefore if there is a diseased *will* in disagreement with the rest of the body in the organ of the skin, we may hold it in check by applying cold as long as the generation of warmth, a normal *will*, can be induced by it." P. 1: "If we are forced to the conviction that there must be a *determining principle* — a *will*, in every vital action, by which the development suited to the whole organism is occasioned, and each metamorphosis of the parts conditioned, in harmony with the whole individuality, and likewise that there is a something capable of being determined and developed," &c. &c. — P. 11: "With respect to individual life, the element which determines, the organic *will*, if it is to rest satisfied, must be able to attain what it wants from that which has to be determined. This occurs even when the vital movements are over-excited, as in inflammation: something new is formed, the noxious element is expelled; new plastic materials are meanwhile conveyed through the arteries, more venous blood is carried off, until the process of inflammation is finished and the organic *will* satisfied. It is however possible to excite this *will* to such a

degree, as to make satisfaction impossible. This exciting cause (or stimulus) either acts directly upon the particular organ (poison, contagion) or it affects the whole life; and this life then begins to make the most strenuous efforts to rid itself of the noxious element or to modify the disposition of the organic *will*, and provokes critical vital activity in particular parts (inflammations) or yields to the unappeased *will*." — P. 12: "The insatiable *will* acts destructively upon the organism unless either (*a*) the whole life, in its efforts to attain unity (tendency to adapt means to end), produces other activities requiring satisfaction (*crises et lyses*) which hold that *will* in check — called decisive (*crises completæ*) when quite successful; *crises incompletæ*, when only partially so — or (*b*) some other stimulus (medicine) produces another *will* which represses the diseased one. If we place this in one and the same category with the *will* of which we have become conscious through our own representations, and bear in mind that here there can be no question of more or less distant resemblance, we gain the conviction that we have grasped the fundamental conception of the *one* unlimited, therefore indivisible, life which, according to its different manifestations in various more or less endowed and exercised organs, is just as able to make hair grow on the human body as to combine the most sublime representations. We see that the most violent passion — unsatisfied *will* — may be checked by more or less strong excitement," &c. &c. — P. 18: "The determining element — *this organic will without representation*, this tendency to preserve the organism as a unity — is induced by outward temperature to modify its activity now in the same, now in a remoter organ. Every manifestation of life, however, whether in health or in disease, is a manifestation of the *organic will: this will determines vegetation:* in a healthy condition, in harmony with the unity of the whole; in an unhealthy one ... it is induced *not to will* in harmony with that unity" ... — P. 23: "Cold suddenly applied to the skin suppresses its function (chill); cold drinks check the *organic will* in the digestive organs and thereby intensify that of the skin and produce perspiration; just so with the diseased *organic will*: cold checks cutaneous eruptions," &c. &c. — P. 33: "Fever is the complete participation of the whole vital process in a diseased *will*, *i.e.* it is to the entire vital process what inflammation is to particular organs — the effort of our vitality to form something definite, in order to content the diseased *will* and remove the noxious element. — We call this process of

formation *crisis* or *lysis* (turning-point or release). The first perception of the pernicious element which causes the diseased *will*, affects the individuality just in the same way as a noxious element apprehended by our senses, before we have brought to clear representation the entire relation in which it stands to our individuality and the means of removing it. It creates terror and its consequences, a standstill of the vital process in the *parenchyma*, especially in the parts directed towards the outer world; in the skin, and in all the motor muscles belonging to the entire individuality (outer body): shuddering, chills, trembling, pains in the limbs, &c. &c. The difference between them is, that in the latter case the noxious element, either at once or gradually, becomes clear representation, because it is compared with the individuality by means of all the senses, so that its relation to that individuality can be determined, and the means of protection against it (disregard, flight, warding off, defence, &c.) be brought to a *conscious will*; whereas, in the former case, we remain unconscious of that noxious element, and it is life alone (or Nature's curative power) which is striving to remove the noxious element and thereby to content the diseased *will*. Nor must this be taken for a simile; it is, on the contrary, a true description of the manifestation of life." — P. 58: "We must however always bear in mind, that cold acts here as a powerful stimulus to check or moderate the diseased *will* and to rouse in its place a natural *will*, accompanied by general warmth." —

In almost every page of this book similar expressions are to be found. In the second of the Essays I have named, Brandis no longer combines the explanation by the will so universally with each separate analysis, probably in consideration that this explanation is properly speaking, a metaphysical one. Nevertheless he maintains it entirely and completely, giving it even all the more distinct and decided expression, wherever he states it. Thus, for instance, in § 68 *et seq.* he speaks of an "*unconscious will*, which cannot be separated from the conscious one," and is the *primum mobile* of all life, as well in plants as in animals; for, in these, it is a desire and aversion manifesting itself in all the organs which determines all their vital processes, secretions, &c. &c. — §. 71: "All convulsions prove that the manifestation of the will can take place without distinct power of representation." — §. 72: "Everywhere do we meet with a spontaneous, uncommunicated activity, now determined by the sublimest human free will, now by animal desire and aversion, now again by simple, more

vegetative requirements; which activity, in order to maintain itself, calls forth several other kinds of activity in the unity of the individual." — P. 96: "A creative, spontaneous, uncommunicated activity shows itself in every vital manifestation." ...— "The third factor in this individual creation is the *will, the individual's life itself*." ...— "The nerves are the conductors of this individual creation: by their means form and mixture are varied according to desire and aversion." — P. 97: "Assimilation of foreign substance ... makes the blood.... It is not an absorption or an exudation of organic matter; ... on the contrary, here the sole factor of the phenomenon is in all cases *the creative will*, a life which cannot be brought back to any sort of imparted movement." —

When I wrote this (1835) I was still *naïf* enough seriously to believe that Brandis was unacquainted with my work, or I should not allude here to his writings; for they would then be merely a repetition, application and carrying out of my own doctrine on this point, not a corroboration of it. But I thought I might safely assume that he did not know me, because he has not mentioned me anywhere and because if he had known me, literary honesty would have made it his imperative duty not to remain silent concerning the man from whom he had borrowed his chief fundamental thought, the more so as he saw that man then enduring unmerited neglect, by his writings being generally ignored — a circumstance which might be construed as favourable to fraud. Add to this, that it lay in Brandis' own interest as a writer, and would therefore have shown sagacity on his part, to have appealed to me as an authority. For the fundamental doctrine propounded by him is so striking and paradoxical, that even his Göttingen reviewer is amazed and hardly knows what to think of it; yet such a doctrine as this was left without foundation either through proof or induction, nor did Dr. Brandis establish its relation to the whole of our knowledge of Nature: he simply asserted it. I imagined therefore that it was by the peculiar gift of divination, which enables eminent physicians to see and do the right thing in cases of illness, that he had been led to this view, without being able to give a strict and methodical account of the grounds of this really metaphysical truth, although he must have seen how greatly it is opposed to the generally received views. Had he, thought I, been acquainted with my philosophy, which gives far greater extension to this truth, makes it valid for the whole of Nature and founds it both by proof and induction in close

connection with Kant's teaching, from which it proceeds as a final result of excogitation — how gladly must he have availed himself of such confirmation and support, rather than to stand alone by an unheard-of assertion which was never further carried out and, with him, never went beyond bare assertion. Such were the reasons that led me to believe myself entitled to take for granted Dr. Brandis' ignorance of my book.

Since then however I have become better acquainted with German scientists and Copenhagen Academicians, to which body Dr. Brandis belonged, and have gained the conviction that he knew me very well indeed. I stated my reasons for arriving at this conviction already in 1844 in the 2nd vol. of "Die Welt als Wille und Vorstellung,"[28] so that, as the subject is by no means edifying, it is needless to repeat them here; I will merely add that I have since been assured on trustworthy authority that Dr. Brandis not only knew my work but even possessed it, as it was found among his property after his death. — The unmerited obscurity to which writers like myself are long condemned, encourages such people to appropriate their thoughts without so much as naming them.

Another medical authority has carried this even farther; for, not content with the thought alone, he has appropriated to himself the expression of it also. I allude to Professor Anton Rosas of the University of Vienna, whose entire § 507 in the 1st vol. of his Textbook of Ophthalmology[29] (1830) is copied word for word from pp. 14-16 of my treatise "On Vision and Colours" (1816) without any mention whatever of me, or even the slightest hint that he is using the words of another. This sufficiently accounts for the care he has taken not to mention my treatise among the lists of twenty-one writings on Colours and forty on the Physiology of the Eye, which he gives in §§ 542 and 567; a caution which was however all the more advisable, as he had appropriated to himself a good deal more out of that pamphlet without mentioning me. All that is referred, for instance, in § 526 to 'them' (*man*), is only applicable to me. His entire § 527 is copied almost literally from my pp. 59 and 60. The theory which he introduces without further ceremony in § 535 by the word "evidently": that is, that yellow is 3/4 and violet 1/4 of the eye's activity, never was 'evident' to anyone until I made it so; even to this day it is a truth known to few and acknowledged by fewer still, and much is yet wanting — for example, that I should be dead and buried — ere it be possible to call it 'evident' without further ceremony. The matter will even have to wait till after my death to be seriously sifted,

since a close investigation might easily bring to 'evidence' the real difference between Newton's theory of colours and my own, which is simply that his is false, and mine true: a discovery which could not fail to mortify my contemporaries. Wherefore, according to ancient custom, all serious examination into the question is wisely postponed for these few years. Professor Rosas knew no such policy as this and, as the matter was not alluded to anywhere, thought himself entitled, like the Danish Academician, to claim it as lawful prey (*de bonne prise*). Evidently North and South German honesty had not yet come to a satisfactory understanding. — Moreover the whole contents of §§ 538, 539 and 540 in Professor Rosas' book are taken from my pamphlet, nay even in great part copied word for word from my § 13. Still once, where he stands in need of a voucher for a fact, he finds himself obliged to refer to my treatise: that is, in his § 531; and it is most amusing to see the way in which he even brings in the numerical fractions used by me, as a result of my theory, to express all colours. It had probably occurred to him, that appropriating them quite *sans façon* might be a delicate matter, so he says, p. 308: "*If we wished* to express in numbers the first-mentioned relation in which colours stand to white, assuming white to be = 1, the following scale of proportion might *by the way* be adopted (as has already been done by Schopenhauer):

yellow = 3/4
orange = 2/3
red = 1/2
green = 1/2
blue = 1/3
violet = 1/4
black = 0"

Now I should like to know how anyone could do this *by the way*, without having first thought out my whole colour-theory, to which alone these numbers refer, and apart from which they are mere abstract numbers without meaning; above all, how anyone could do it who, like Professor Rosas, professes to be a follower of Newton's colour-theory, with which these numbers are in direct contradiction? Finally, I should like to know how it came, that during the thousands of years in which men have thought and written, no one but myself and Professor Rosas should ever have thought of using just these particular fractions to denote colours? For the

words I have quoted above tell us, that he would have stated those fractions precisely as he has done, even had I not chanced to do it ‘already’ fourteen years before and thus needlessly anticipated his statement; they also tell us, that all that is required is ‘*to wish*,’ in order to do so. Now it is precisely in these numerical fractions that the secret of colours lies: by them alone can we rightly solve the mystery of their nature and of their difference from one another. — I should however be heartily glad, were plagiarism the worst kind of dishonesty that defiled German literature; there are others far more mischievous, which penetrate more deeply, and to which plagiarism bears the same proportion as picking pockets in a mild way to capital crime. I allude to that mean, despicable spirit, whose loadstar is personal interest, when it ought to be truth, and in which the voice of intention makes itself heard beneath the mask of insight. Double-dealing and time-serving are the order of the day. Tartuffe comedies are performed without *rouge*; nay, Capuchin sermons are preached in halls consecrated to Science; enlightenment, that once revered word, has become a term of opprobrium; the greatest thinkers of the past century, Voltaire, Rousseau, Locke, Hume, are slandered — those heroes, ornaments and benefactors of mankind, whose fame, diffused throughout both hemispheres, can only be increased, if by anything, by the fact that wherever and whenever obscurantists show themselves, it is as their bitterest enemies — and with good reason. Literary *coteries* and associations are formed to deal out praise and blame, and spurious merit is then trumpeted forth and extolled, while sterling merit is slandered or, as Göthe says, “*secreted, by means of an inviolable silence, in which sort of inquisitorial censure the Germans have attained great proficiency*.”[30] The motives and considerations however from which all this proceeds, are of too low a nature for me to care to enumerate them in detail. But what a difference there is between periodicals such as the “Edinburgh Review,” in which gentlemen of independent means are induced to write by a genuine interest in the subjects treated, and which honourably upholds its noble motto taken from Publius Syrus: *Judex damnnatur cum nocens absolvitur*, and our mean-spirited, disingenuous, German literary journals, full of considerations and intentions, that are mostly compiled for the sake of pay by hired editors, and ought properly to have for their motto: *Accedas socius laudes, lauderis, ut absens*.[31] Now, after twenty years, do I understand what Göthe said to me at Berka in 1814. As I found him reading Madame de Staël’s “*De l’Allemagne*,” I remarked in course of conversation

that she had given too exaggerated a description of German honesty and one that might mislead foreigners. He laughed and said: “Yes, to be sure, they will not secure their baggage behind and will have it cut off.” He then added in a graver tone: “But one has to know German literature in order to realise the full extent of German dishonesty.” — All well and good! But the most revolting kind of dishonesty in German literature is that of the time-servers, who pass themselves off for philosophers, while in reality they are obscurantists. The word ‘time-serving’ no more needs explanation than the thing needs a proof; for anyone who had the face to deny it would furnish strong evidence in support of my present argument. Kant taught, that man ought to use his fellow-man only as an end, never as a means: he did not think it necessary to say, that philosophy ought only to be dealt with as an end, never as a means. Time-serving may after all be excused under every garb, the cowl as well as the ermine, save only the philosopher’s cloak (*Tribonion*); for he who has once assumed this, has sworn allegiance to truth, and from that moment every other consideration, no matter of what kind, becomes base treachery. Therefore it was that Socrates did not shun the hemlock, nor Bruno the stake, while ‘for a piece of bread these men will transgress.’ Are they too short-sighted to see posterity close at hand, with the history of philosophy at its side, recording two lines of bitter condemnation with unflinching hand and iron pen in its immortal pages? Or has this no sting for them? — Well to be sure, if it comes to the worst, ‘*après moi le déluge*’ may be pronounced; but as to ‘*après moi le mépris*,’ that is a more difficult matter. Therefore I fancy they will answer that austere judge as follows: “Ah, dear posterity and history of philosophy! you are quite wrong to take us in earnest; we are not philosophers at all, Heaven forbid! No, we are only professors of philosophy, mere servants of the state, mere philosophers in jest. You might as well drag puppet-knights in pasteboard armour into a real tournament.” Then the judge will most likely see how matters stand, erase all their names, and confer upon them the *beneficium perpetui silentii*.

From this digression — to which I had been led away eighteen years ago, by the cant and time-serving I then witnessed, though they were not nearly as flourishing then as they are now — I return to that part of my doctrine which Dr. Brandis has confirmed, though he did not originate it, in order to add a few explanations with which I shall then connect some further corroborations it has since received from Physiology.

The three assumptions which are criticised by Kant in his Transcendental Dialectic under the names of Ideas of Reason, and have in consequence since been set aside in theoretical philosophy, had always stood in the way of a deeper insight into Nature, until that great thinker brought about a complete transformation in philosophy. That supposed Idea of Reason, the soul: that metaphysical being, in it whose absolute singleness knowing and willing were knit and blended together to eternal, inseparable unity, was an impediment of this sort for the subject-matter of this chapter. As long as it lasted, no philosophical Physiology was possible: the less so, as its correlate, real, purely passive Matter, had necessarily also to be assumed together with it, as the substance of the body.[32] It was this Idea of Reason, the soul, therefore, that caused the celebrated chemist and physiologist, George Ernest Stahl, at the beginning of the last century to miss the discovery of the truth he so nearly approached and would have quite reached, had he been able to put that which is alone metaphysical, the bare *will* — as yet without intellect — in the place of the *anima rationalis*. Under the influence of this Idea of Reason however, he could not teach anything but that it is this simple, rational soul which builds itself a body, all whose inner organic functions it directs and performs, yet has no knowledge or consciousness of all this, although knowledge is the fundamental destination and, as it were, the substance, of its being. There was something absurd in this doctrine which made it utterly untenable. It was superseded by Haller's Irritability and Sensibility, which, to be sure, are taken in a purely empirical sense, but, to make up for this, are also two *qualitates occultæ*, at which all explanation ceases. The movement of the heart and of the intestines was now attributed to Irritability. But the *anima rationalis* still remained in undiminished honour and dignity as a visitor at the house of the body.[33]— "Truth lies at the bottom of a well," said Democritus; and the centuries with a sigh, have repeated his words. But small wonder, if it gets a rap on the knuckles as soon as it tries to come out!

The fundamental truth of my doctrine, which places that doctrine in opposition with all others that have ever existed, is the complete separation between the will and the intellect, which all philosophers before me had looked upon as inseparable; or rather, I ought to say that they had regarded the will as conditioned by, nay, mostly even as a mere function of, the intellect, assumed by them to be the fundamental substance of our spiritual being. But this separation, this analysis into two heterogeneous elements, of

the *ego* or *soul*, which had so long been deemed an indivisible unity, is, for philosophy, what the analysis of water has been for chemistry, though it may take time to be acknowledged. With me, that which is eternal and indestructible in man, therefore, that which constitutes his vital principle, is not *the soul*, but — if I may use a chemical term — its radical: and this is *the will*. The so-called soul is already a compound: it is the union of the will and the intellect (νούς). This intellect is the secondary element, the *posterius* of the organism and, as a mere cerebral function, is conditioned by the organism; whereas the will is what is primary, the *prius* of the organism, which is conditioned by it. For the will is that thing in itself, which only becomes apparent as an organic body in our representation (that mere function of the brain): it is only through the forms of knowledge (or cerebral function), that is, only in our representation — not apart from that representation, not immediately in our self-consciousness — that our body is given to each of us as a thing which has extension, limbs and organs. As the actions of our body are only acts of volition portraying themselves in representation, so likewise is their substratum, the shape of that body, in the main the portrait of the will: so that, in all the organic functions of our body, the will is just as much the *agent* as in its external actions. True Physiology, at its highest, shows the spiritual (the intellectual) in man to be the product of the physical in him, and no one has done this so thoroughly as Cabanis; but true Metaphysic teaches us, that the physical in man is itself mere product, or rather phenomenon, of a spiritual (the will); nay, that Matter itself is conditioned by representation, in which alone it exists. Perception and reflection will more and more find their explanation through the organism; but not the will, by which conversely the organism is explained, as I shall show in the following chapter. First of all therefore I place *the will, as thing in itself* and quite primary; secondly, its mere visibility, its objectification: *i.e.* the *body*; thirdly, the *intellect*, as a mere function of one part of that body. This part is itself the objectified will to know (the will to know having entered into representation), since the will needs knowledge to attain its own ends. Now the entire world as representation, together with the body itself therefore, inasmuch as it is a perceptible object, nay, Matter in general as existing only in representation, — all this, I say, is again conditioned by that function; for, duly considered, we cannot possibly conceive an objective world without a Subject, in whose consciousness it is present. Thus knowledge and matter (Subject and Object) exist only

relatively one for the other and constitute *phenomenon*. The whole thing therefore, owing to the radical change made by me, stands in a different light from that in which it has hitherto been regarded.

As soon as it is directed outwardly and acts upon a recognised object, as soon therefore as it has passed through the medium of knowledge, we all recognise the *will* at once to be the active principle, and call it by its right name. Yet it is no less active in those inner processes which have preceded such outward actions as their conditions: in those, for instance, which create and maintain organic life and its substratum; and the circulation of the blood, secretion, digestion, &c. &c., are its work likewise. But just because the will was only recognised as the active principle in those cases in which it abandons the individual whence it proceeds, in order to direct itself towards the outer world — now presenting itself precisely for this end, as perception — knowledge has been taken for its essential condition, its sole element, nay, as the substance of which it consists: and hereby was perpetrated the greatest ὕστερον πρότερον that has ever been.

But before all things we must learn to distinguish will [*Wille*] (*voluntas*) from free-will [*Willkühr*] (*arbitrium*)[34] and to understand that the former can subsist without the latter; this however presupposes my whole philosophy. The will is called free-will when it is illumined by knowledge, therefore when the causes which move it are motives: that is, representations. Objectively speaking this means: when the influence from outside which causes the act, has a *brain* for its mediator. A motive may be defined as an external stimulus, whose action first of all causes an *image* to arise in the *brain*, through the medium of which the will carries out the effect proper — an outward action of the body. Now, in the human species however, the place of such an image as this may be taken by a conception drawn from former images of this kind by dropping their differences, which conception consequently is no longer perceptible, but merely denoted and fixed by words. As the action of motives accordingly does not depend upon contact, they can try their power on the will against each other: in other words, they permit a certain choice which, in animals, is limited to the narrow sphere of that which has *perceptible* existence for them; whereas, in man, its range comprises the vast extent of all that is *thinkable*: that is, of his conceptions. Accordingly we designate as *voluntary* those movements which are occasioned, not by *causes* in the narrowest sense of the word, as in inorganic bodies, nor even by *mere stimuli*, as in plants, but by *motives*.[35]

These motives however presuppose an *intellect* as *their mediator*, through which causality here acts, without prejudice to its entire necessity in all other respects. Physiologically, the difference between stimulus and motive admits also of the following definition. The stimulus provokes *immediate* reaction, which proceeds from the very part on which the stimulus has acted; whereas the motive is a stimulus that has to go a roundabout way through the brain, where its action first causes an image to arise, which then, but not till then, provokes the consequent reaction, which is now called an act of volition, and *voluntary*. The distinction between voluntary and involuntary movement does not therefore concern what is essential and primary — for this is in both cases the will — but only what is secondary, the rousing of the will's manifestation: it has to do with the determination whether *causes* proper, *stimuli* or *motives* (*i.e.* causes having passed through the medium of knowledge) are the guidance under which that manifestation takes place. It is in human consciousness, — differing from that of animals by not only containing perceptible representations but also abstract conceptions independent of time-distinctions, which act simultaneously and collaterally, whereby deliberation, *i.e.* a conflict of motives, becomes possible — it is in human consciousness, I say, that free-will (*arbitrium*) in its narrowest sense first makes its appearance; and this I have called elective decision. It nevertheless merely consists in the *strongest* motive for a given individual character overcoming the others and thus determining the act, just as an impact is overcome by a stronger counter-impact, the result thus ensuing with precisely the same necessity as the movement of a stone that has been struck. That all great thinkers in all ages were decided and at one on this point, is just as certain, as that the multitude will never understand, never grasp, the important truth, that the work of our freedom must not be sought in our individual actions but in our very existence and nature itself. In my prize-essay on Freedom of the Will, I have shown this as clearly as possible. The *liberum arbitrium indifferentiæ* which is assumed to be the distinctive characteristic of movements proceeding from *the will*, is accordingly quite inadmissible: for it asserts that effects are possible without causes.

As soon therefore as we have got so far as to distinguish *will* [*Wille*] from *free-will* [*Willkühr*], and to consider the latter as a particular kind or particular phenomenon of the former, we shall find no difficulty in recognising the will, even in unconscious processes. Thus the assertion,

that all bodily movements, even those which are purely vegetative and organic, proceed from *the will*, by no means implies that they are voluntary. For that would mean that they were occasioned by motives; but motives are representations, and their seat is the brain: only those parts of our body which communicate with the brain by means of the nerves, can be put in movement by the brain, consequently by motives, and this movement alone is what is called voluntary. The movement of the inner economy of the organism, on the contrary, is directed, as in plant-life, by *stimuli*; only as, on the one hand, the complex nature of the animal organism necessitated an outer sensorium for the apprehension of the outer world and the will's reaction on that outer world, so, on the other hand, did it necessitate a *cerebrum abdominale*, the sympathetic nervous system, in order to direct the will's reaction upon inner stimuli likewise. We may compare the former to a Home Ministry, the latter to a Foreign Office; but the will remains the omnipresent Autocrat.

The progress made in Physiology since Haller has placed beyond doubt, that not only those actions which are consciously performed (*functiones animales*), but even vital processes that take place quite unconsciously (*functiones vitales et naturales*), are directed throughout by the *nervous system*. Likewise that their only difference, as far as our consciousness of them is concerned, consists in the former being directed by nerves proceeding from the brain, the latter by nerves that do not directly communicate with that chief centre of the nervous system — mainly directed towards the outside — but with subordinate, minor centres, with the nerve-knots, the ganglia and their net-work, which preside as it were like vice-gerents over the various departments of the nervous system, directing those internal processes that follow upon internal stimuli, just as the brain directs the external actions that follow upon external motives, and thus receiving impressions from inside upon which they react correspondingly, just as the brain receives representations on the strength of which it forms resolutions; only each of these minor centres is confined to a narrower sphere of action. Upon this rests the *vita propria* of each system, in referring to which Van Helmont said that each organ has, as it were, its own *ego*. It accounts also for life continuing in parts which have been cut off the bodies of insects, reptiles, and other inferior animals, whose brain has no marked preponderance over the ganglia of single parts; and it likewise explains how many reptiles are able to live for weeks, nay even

months, after their brain has been removed. Now, if our surest experience teaches us that *the will*, which is known to us in most immediate consciousness and in a totally different way from the outer world, is the real agent in actions attended by consciousness and directed by the chief centre of the nervous system; how can we help admitting that those other actions which, proceeding from that nervous system but obeying the direction of its subordinate centres, keep the vital processes constantly going, must also be manifestations of *the will*? Especially as we know perfectly well the cause because of which they are not, like the others, attended by consciousness: we know, that is to say, that all consciousness resides in the brain and therefore is limited to such parts as have nerves which communicate directly with the brain; and we know also that, even in these, consciousness ceases when those nerves are severed. By this the difference between all that is conscious and unconscious and together with it the difference between all that is voluntary and involuntary in the movements of the body is perfectly explained, and no reason remains for assuming two entirely different primary sources of movement: especially as *principia præter necessitatem non sunt multiplicanda*. All this is so obvious, that, on impartial reflection from this standpoint, it seems almost absurd to persist in making the body serve two masters by deriving its actions from two radically different origins and then ascribing on the one hand the movements of our arms and legs, of our eyes, lips, throat, tongue and lungs, of the facial and abdominal muscles, to the will; while on the other hand the action of the heart, the movements of the veins, the peristaltic movements of the intestines, the absorption by the intestinal villi and glands and all those movements which accompany secretion, are supposed to proceed from a totally different, ever mysterious principle of which we have no knowledge, and which is designated by names such as vitality, archeus, *spiritus animales*, vital energy, instinct, all of which mean no more than *x*.[36]

It is curious and instructive to see the trouble that excellent writer, Treviranus[37] takes, to find out in the lower animals, such as *infusoria* and *zoophyta*, which movements are voluntary, and which are what he calls automatic or physical, *i.e.* merely vital. He founds his inquiry upon the assumption that he has to do with two primarily different sources of movement; whereas in truth they all proceed from the will, and the whole difference consists in their being occasioned by stimuli or by motives, *i.e.* in their having a brain for their medium or not; and the stimulus may again

be merely interior or exterior. In several animals of a higher order — crustaceans and even fishes — he finds that the voluntary and vital movements, for instance locomotion and respiration, entirely coincide: a clear proof that their origin and essence are identical. He says p. 188: "In the family of the *actinia*, star-fishes, sea-urchins, and *holothuriæ* (*echinodermata pedata Cuv.*), it is evident that the movement of the fluids depends upon the will of the animals and that it is a means of locomotion." Then again p. 288: "The gullet of mammals has at its upper end the pharynx, which expands and contracts by means of muscles resembling voluntary muscles in their formation, yet which do not obey the will." Here we see how the limits of the movements proceeding from the will and of those assumed to be foreign to it, merge into one another. *Ibid.*, p. 293: "Thus movements having all the appearance of being voluntary, take place in the stomachs of ruminants. They do not however always stand in connection with the ruminating process only. Even the simpler human stomach and that of many animals only allows free passage to what is digestible through its lower orifice, and rejects what is indigestible by vomiting."

There is moreover special evidence that the movements induced by stimuli (involuntary movements) proceed from the will just as well as those occasioned by motives (voluntary movements): for instance, when the same movement follows now upon a stimulus, now again upon a motive, as is the case when the pupil of the eye is contracted. This movement, when caused by increased light, follows upon a stimulus; whereas, when occasioned by the wish to examine a very small object minutely in close proximity, it follows upon a motive; because contracting the pupil enables us to see things distinctly even when quite near to us, and this distinctness may be increased by our looking through a hole pierced in a card with a pin; conversely, the pupil is dilated when we look at distant objects. Surely the same movement of the same organ is not likely to proceed alternately from two fundamentally different sources. — E. H. Weber[38] relates that he discovered in himself the power of dilating and contracting at will the pupil of one of his eyes, while looking at the same object, so as to make that object appear now distinct, now indistinct, while the other eye remained closed. — Joh. Müller[39] also tries to prove that the will acts upon the pupil.

The truth that the innermost mainspring of unconsciously performed vital and vegetative functions is the will, we find moreover confirmed by

the consideration, that even the movement of a limb recognised as voluntary, is only the ultimate result of a multitude of preceding changes which have taken place inside that limb and which no more enter into our consciousness than those organic functions. Yet these changes are evidently that which was first set in motion by the will, the movement of the limb being merely their remote consequence; nevertheless this remains so foreign to our consciousness that physiologists try to reach it by means of such hypotheses as these: that the sinews and muscular fibre are contracted by a change in the cellular tissue wrought by a precipitation of the blood-vapour in that tissue to serum; but that this change is brought about by the nerve's action, and this — by *the will*. Thus, even here, it is not the change which proceeded originally from the will which comes into consciousness, but only its remote result; and even this, properly speaking, only through the special perception of the brain in which it presents itself together with the whole organism. Now by following the path of experimental research and hypotheses physiologists would never have arrived at the truth, that the last link in this ascending causal series is *the will*; it is known to them, on the contrary, in quite a different way. The solution of the enigma comes to them in a whisper from outside the investigation, owing to the fortunate circumstance that the investigator is in this case at the same time himself the object of the investigation and by this learns the secret of the inward process, his explanation of which would otherwise, like that of every other phenomenon, be brought to a standstill by an inscrutable force. And conversely, if we stood in the same inward relation towards every natural phenomenon as towards our own organism, the explanation of every natural phenomenon, as well as of all the properties of every body, would likewise ultimately be reduced to a will manifesting itself in them. For the difference does not reside in the thing itself, but in our relation to the thing. Wherever explanation of the physical comes to an end, it is met by the metaphysical; and wherever this last is accessible to immediate knowledge, the result will be, as here, the will. That even those parts of the body whose movements do not proceed from the brain, do not follow upon motives, and are not voluntary, are nevertheless ruled and animated by the will, is also shown by their participation in all unusually violent movements of the will, *i.e.* emotions and passions. We see, for instance, the quickened pulse in joy or alarm, the blush in embarrassment, the cheek's pallor in terror or in suppressed anger, the tears of sorrow, the difficult breathing and increased

activity of the intestines in terror, watering of the mouth at the sight of dainties, nausea occasioned by that of loathsome objects, strongly accelerated circulation of the blood and even altered quality of bile through wrath, and of saliva through violent rage: this last even to the degree, that an excessively irritated dog may communicate hydrophobia by its bite without being itself affected with rabies, or even then contracting the disease — and the same is also asserted of cats and of cocks. The organism is further deeply undermined by lasting grief, and may be mortally affected by fright as well as by sudden joy. On the other hand, all those inner processes and changes which only have to do with the intellect and do not concern the will, however great may be their importance, remain without influence upon the machinery of the organism, with the one exception, that mental activity, prolonged to excess, fatigues and gradually exhausts the brain and finally undermines the organism. This again confirms the fact that the intellect is of a secondary character, and merely the organic function of a single part, a product of life; not the innermost kernel of our being, not the thing in itself, not metaphysical, incorporeal, eternal, like the will: the will never tires, never grows old, never learns, never improves by practice, is in infancy what it is in old age, eternally one and the same, and its character in each individual is unchangeable. Being essential moreover, it is likewise immutable, and therefore exists in animals as it does in us; for it does not, like the intellect, depend upon the perfection of the organization, but is in every essential respect in all animals the same thing which we know so intimately. Accordingly animals have all the feelings which belong to man: joy, grief, fear, anger, love, hate, desire, envy, &c. &c. The great difference between man and the brute creation consists exclusively in the degrees of perfection of the intellect. This however is leading us too far from our subject, so I refer my readers to my chief work, vol. ii. chap. 19, *sub.* 2.

After the cogent reasons just given in favour of the primary *agens* in the inward machinery of the organism being the very same will which rules the outward actions of the body and only reveals itself as the will in this passage through consciousness because here it needs the mediation of outwardly directed knowledge, we shall not be astonished to find that other physiologists besides Brandis had, by means of strictly empirical research, also recognised this truth more or less clearly. Meckel,[40] in his "Archiv für die Physiologie," arrives quite empirically and impartially at the conclusion, that vegetative existence [in animals], the first growth of the embryo, the

assimilation of nourishment and plant-life, ought properly to be considered as manifestations of the will, nay, that even the inclination of the magnetic needle seems to be something of the same kind. "The assumption," he says, "of a certain free will in every vital movement may perhaps be justified." "Plants appear to seek light voluntarily," &c. &c. This book is dated 1819 just after the appearance of my work; and as, to say the least, it is doubtful whether it had any influence upon him or whether he was even aware of its existence, I class these utterances among the independent empirical confirmations of my doctrine. Burdach also,[41] in his great work on Physiology, arrives by a completely empirical road at the conclusion, that "self-love is a force belonging to all things indiscriminately." He points it out, first in animals, then in plants, and lastly in inanimate bodies. But what is self-love after all, if not the will to preserve our existence, the will to live? Under the heading "Comparative Anatomy," I shall quote a passage from the same book, which confirms my view still more decidedly. That the doctrine, which teaches that the will is the vital principle, has begun to spread even to the wider circles of medical science and to meet with a favourable reception from its younger representatives, I notice with particular pleasure in the theses sustained by Dr. Von Sigriz on taking his degree at Munich (August, 1835), which commence as follows: 1. *Sanguis est determinans formam organismi se evolventis.* 2. *Evolutio organica determinatur vitæ internæ actione et* voluntate.

Lastly, a very remarkable and unexpected corroboration of this part of my doctrine has to be mentioned, which has recently been communicated from ancient Hindoo philosophy by Colebrook. In his exposition of the philosophical schools of the Hindoos,[42] he quotes the following as the doctrine of the Nyaga school: "Volition, Yatna, effort or manifestation of the Will, is a self-determination to act which gives satisfaction. Desire is its occasion, perception its motive. Two kinds of perceptible effort of the will are distinguished: that which springs from desire which seeks the agreeable, and that which springs from aversion which shuns the repulsive. Another species, which escapes sensation and perception, but is inferred from analogy of spontaneous acts, comprises animal functions, having for a cause the vital, unseen power." Here the words "animal functions" are evidently used, not in a physiological, but in a popular sense: so that here organic life is unquestionably derived from the will. We find a similar statement in Colebrook's Report on the Vedas[43] where he says: "*Asu is unconscious*

volition, which occasions an act necessary to the support of life, as breathing, &c."

Moreover my reduction of vital energy to the will by no means interferes with the old division of its functions into reproductive force, irritability and sensibility. This division remains a deep view of their difference, and gives occasion for interesting observations.

The faculty of reproduction, objectified in the cellular tissue of plants, constitutes the chief characteristic of plants and the vegetative element in Man. Where we find it predominant to excess in human beings, we assume them to be phlegmatic, dull, indolent, obtuse (Bœotians); though this assumption does not always meet with confirmation. *Irritability*, objectified in the muscular tissue, constitutes the chief characteristic of Animals and the animal element in Man. Where it predominates to excess, dexterity, strength, bravery, that is, fitness for bodily exertion and for war, is usually to be found (Spartans). Nearly all warm-blooded animals and even insects far surpass Man in irritability. It is by irritability that animals are most vividly conscious of their existence; wherefore they exult in manifesting it. There is even still a trace of that exultation perceptible in Man, in dancing. *Sensibility*, objectified in the nerves, is Man's chief characteristic, and constitutes what is properly human in him. In this no animal can in the remotest degree compare with Man. Where it predominates to excess, it produces *genius* (Athenians). Accordingly a man of genius is in a higher degree a *man*. This explains why some men of genius have been unwilling to recognise other men, with their monotonous physiognomies and universal stamp of commonplace mediocrity, as human beings: for in them they did not find their equals and naturally came to the erroneous conclusion that their own was the normal standard. Diogenes sought for men with a lantern in this sense; — in that work of genius, the Koheleth (Ecclesiastes) it is said:[44] "*One* man among a thousand have I found, but one woman among all those have I not found;" and Gracian in his Criticon — perhaps the grandest and most beautiful allegory ever written — says: "But what was strangest of all, in the whole country, even in the most populous cities, they did not meet with a single *man*; on the contrary these cities were inhabited by lions, tigers, leopards, wolves, foxes, apes, oxen, asses, pigs, — nowhere was there a man! They only made out after a time that the few existing human beings, in order to hide themselves and not to witness what was going on, had retired to those desert places which ought to have been

the dwellings of wild beasts.” The same reason indeed accounts for the peculiar inclination of all men of genius for solitude, to which they are driven by their difference from the rest, and for which their own inner wealth qualifies them. For, with humanity it is as with diamonds, the extraordinarily great ones alone are fitted to be *solitaires*, while those of ordinary size have to be set in clusters to produce any effect.

Even the three *Gunas*, or fundamental qualities of the Hindoos, tally with the three physiological fundamental forces. *Tamas-Guna*, obtuseness, stupidity, corresponds to reproductive power; *Rajas-Guna*, passionateness, to irritability; and *Sattwa-Guna*, wisdom and virtue, to sensibility. When however they add to this, that Tamas-Guna is the fate of animals, Rajas-Guna the fate of man, and Sattwa-Guna that of the Gods, this is to be taken in a mythological, rather than physiological sense.

In Chapter 20th of the 2nd Vol. of my chief work entitled “Objectification of the Will in the Animal Organism,” I have likewise treated the argument of the present chapter; therefore I advise my readers to read it after this, as a complement to what is here given.[45]

I may observe, that the passages I have quoted from pp. 14 and 15 of my Essay on Colours, refer to the first edition.

COMPARATIVE ANATOMY.

Now, from my proposition: that the Will is what Kant calls the "thing in itself"[46] or the ultimate substratum of every phenomenon, I had however not only deduced that the will is the agent in all inner, unconscious functions of the body, but also that the organism itself is nothing but the will which has entered the region of representation, the will itself, perceived in the cognitive form of Space. I had accordingly said that, just as each single momentary act of willing presents itself at once directly and infallibly in the outer perception of the body as one of its actions, so also must the collective volition of each animal, the totality[47] of its efforts, be faithfully portrayed in its whole body, in the constitution of its organism; and that the means supplied by its organisation for attaining the aims of its will must as a whole exactly correspond to those aims — in short, that the same relation must exist between the whole character of its volition and the shape and nature of its body, as between each single act of its will and the single bodily action which carries it out. Even this too has recently been recognised as a fact, and accordingly been confirmed *à posteriori*, by thoughtful zootomists and physiologists from their own point of view and independently of my doctrine: their judgments on this point make Nature testify even here to the truth of my theory.

In Pander and d'Alton's admirable illustrated work[48] we find: "Just as all that is characteristic in the formation of bones springs from the *character* of the animals, so does that character, on the other hand, develop out of their *tendencies and desires*. These *tendencies and desires* of animals, which are *so vividly expressed* in their whole organisation and of which that organisation only appears to be the medium, cannot be explained by special primary forces, since we can only deduce their inner reason from the general life of Nature." By this last turn the author shows indeed that he has arrived at the point where, like all other investigators of Nature, he is brought to a standstill by the metaphysical; but he also shows, that up to this point beyond which Nature eludes investigation, *tendencies and desires* (*i.e.* will) were the utmost thing knowable. The shortest expression for his last conclusion about animals would be "As they will, so they are."

The learned and thoughtful Burdach,[49] when treating of the ultimate reason of the genesis of the embryo in his great work on Physiology, bears

witness no less explicitly to the truth of my view. I must not, unfortunately, conceal the fact that in a weak moment, misled Heaven knows by what or how, this otherwise excellent man brings in just here a few sentences taken from that utterly worthless, tyrannically imposed pseudo-philosophy, about 'thought' being what is primary (it is just what is last and most conditioned of all) yet 'no representation' (that is to say, a wooden iron). Immediately after however, under the returning influence of his own better self, he proclaims the real truth (p. 710): "The brain curves itself outwards to the retina, because the central part of the embryo *desires* to take in the impressions of the activity of the world; the mucous membrane of the intestinal canal develops into the lung, because the organic body *desires* to enter into relation with the elementary substances of the universe; organs of generation spring from the vascular system, because the individual only lives in the species, and because the life which has commenced in the individual *desires* to multiply." This assertion of Burdach's, which so entirely agrees with my doctrine, reminds me of a passage in the ancient Mahabharata, which it is really difficult not to regard as a mythical version of the same truth. It is in the third Canto of "Sundas and Upasunda" in Bopp's "Ardschuna's Reise zu Indra's Himmel"[50] (1824); Brahma has just created Tilottama, the fairest of women, who is walking round the circle of the assembled gods. Shiva conceives so violent a longing to gaze at her as she turns successively round the circle, that four faces arise in him according to her different positions, that is, according to the four cardinal points. This may account for Shiva being represented with five heads, as Pansh Mukhti Shiva. Countless eyes arise on every part of Indra's body likewise on the same occasion.[51] In fact, every organ must be looked upon as the expression of a universal manifestation of the will, *i.e.* of one made once for all, of a fixed longing, of an act of volition proceeding, not from the individual, but from the species. Every animal form is a longing of the will to live which is roused by circumstances; for instance, the will is seized with a longing to live on trees, to hang on their branches, to devour their leaves, without contention with other animals and without ever touching the ground: this longing presents itself throughout endless time in the form (or Platonic Idea) of the sloth. It can hardly walk at all, being only adapted for climbing; helpless on the ground, it is agile on trees and looks itself like a moss-clad bough in order to escape the notice of its pursuers. But now let us

consider the matter from a somewhat more methodical and less poetical point of view.

The manifest adaptation of each animal for its mode of life and outward means of subsistence, even down to the smallest detail, together with the exceeding perfection of its organisation, form abundant material for teleological contemplation, which has always been a favourite occupation of the human mind, and which, extended even to inanimate Nature, has become the argument of the Physico-theological Proof. The universal fitness for their ends, the obviously intentional design in all the parts of the organism of the lower animals without exception, proclaim too distinctly for it ever to have been seriously questioned, that here no forces of Nature acting by chance and without plan have been at work, but a will. Now, that a will should act otherwise than under the guidance of knowledge was inconceivable, according to empirical science and views. For, up to my time, as has been shown in the last chapter, *will* and *intellect* had been regarded as absolutely inseparable, nay, the will was looked upon as a mere operation of the intellect, that presumptive basis of all that is spiritual. Accordingly wherever the will acted, knowledge must have been its guide; consequently it must have been its guide here also. But the mediation of knowledge, which, as such, is exclusively directed towards the outside, brings with it, that a will acting by means of it, can only act outwardly, that is, only from *one* being upon *another*. Therefore the will, of which unmistakable traces had been found, was not sought for where these were discovered, but was removed to the outside, and the animal became the product of a will foreign to it, guided by knowledge, which must have been very clear knowledge indeed, nay, the deeply excogitated conception of a purpose; and this purpose must have preceded the animal's existence, and, together with the will, whose product the animal is, have lain outside that animal. According to this, the animal would have existed in representation before existing in reality. This is the basis of the train of thought on which the Physico-theological Proof is founded. But this proof is no mere scholastic sophism, like the Ontological Proof: nor does it contain an untiring natural opponent within itself, like the Cosmological Proof, in that very same law of causality to which it owes its existence. On the contrary, it is, in reality, for the educated, what the Keraunological Proof[52] is for the vulgar,[53] and its plausibility is so great, so potent, that the most eminent and at the same time least prejudiced minds have been deeply entangled in it.

Voltaire, for instance, who, after all sorts of other doubts, always comes back to it, sees no possibility of getting over it and even places its evidence almost on a level with that of a mathematical demonstration. Even Priestley too declares it to be irrefutable.[54] Hume's reflection and acumen alone stood the test, even in this case; in his "Dialogues on Natural Religion,"[55] which are so well worth reading, this true precursor of Kant calls attention to the fact, that there is no resemblance at all between the works of Nature and those of an Art which proceeds according to a design. Now it is precisely where he cuts asunder the *nervus probandi* of this extremely insidious proof, as well as that of the two others — in his Critique of Judgment and in his Critique of Pure Reason — that Kant's merit shines most brilliantly. A very brief summary of this Kantian refutation of the Physico-theological Proof may be found in my chief work.[56] Kant has earned for himself great merit by it; for nothing stands so much in the way of a correct insight into Nature and into the essence of things as this view, by which they are looked upon as having been made according to a preconceived plan. Therefore, if a Duke of Bridgewater offers a prize of high value for the confirmation and perpetuation of such fundamental errors, let it be our task, following in the footsteps of Hume and Kant, to work undauntedly at their destruction, without any other reward than truth. Truth deserves respect: not what is opposed to it. Nevertheless here, as elsewhere, Kant has confined himself to negation; but a negation only takes full effect when it has been completed by a correct affirmation, this alone giving entire satisfaction and in itself dislodging and superseding error, according to the words of Spinoza: *Sicut lux se ipsa et tenebras manifestat, sic veritas norma sui et falsi est*. First of all therefore we say: the world is not made with the help of knowledge, consequently also not from the outside, but from the inside; and next we endeavour to point out the *punctum saliens*[57] of the world-egg. The physico-theological thought, that Nature must have been regulated and fashioned by an intellect, however well it may suit the untutored mind, is nevertheless fundamentally wrong. For the intellect is only known to us in animal nature, consequently as an absolutely secondary and subordinate principle in the world, a product of the latest origin; it can never therefore have been the condition of the existence of that world.[58] Now the will on the contrary, being that which fills every thing and manifests itself immediately in each — thus showing each thing to be its phenomenon — appears everywhere as that which is primary. It is just for this reason, that the explanation of all

teleological facts is to be found in the will of the being itself in which they are observed.

Besides, the Physico-theological Proof may be simply invalidated by the empirical observation, that works produced by animal instinct, such as the spider's web, the bee's honeycomb and its cells, the white ant's constructions, &c. &c., are throughout constituted as if they were the result of an intentional conception, of a wide-reaching providence and of rational deliberation; whereas they are evidently the work of a blind impulse, *i.e.* of a will not guided by knowledge. From this it follows, that the conclusion from such and such a nature to such and such a mode of coming into being, has not the same certainty as the conclusion from a consequent to its reason, which is in all cases a sure one. I have devoted the twenty-seventh chapter of the second volume of my chief work to a detailed consideration of the mechanical instincts of animals, which may be used, together with the preceding one on Teleology, to complete the whole examination of this subject in the present chapter.

Now, if we enter more closely into the above-mentioned fitness of every animal's organisation for its mode of life and means of subsistence, the question that first presents itself is, whether that mode of life has been adapted to the organisation, or *vice versa*. At first sight, the former assumption would seem to be the more correct one; since, in Time, the organisation precedes the mode of life, and the animal is thought to have adopted the mode of existence for which its structure was best suited, making the best use of the organs it found within itself: thus, for instance, we think that the bird flies because it has wings, and that the ox butts because it has horns; not conversely. This view is shared by Lucretius, (always an ominous sign for an opinion):

"Nil ideo quoniam natum est in corpore, ut uti

Possemus; sed, quod natum est, id procreat usum."[59]

Only this assumption does not explain how, collectively, the quite different parts of an animal's organism so exactly correspond to its way of life; how no organ interferes with another, each rather assisting the others and none remaining unemployed; also that no subordinate organ would be better suited to another mode of existence, while the life which the animal really leads is determined by the principal organs alone, but, on the contrary, each part of the animal not only corresponds to every other part, but also to its mode of life: its claws, for instance, are invariably adapted for

seizing the prey which its teeth are suited to tear and break, and its intestinal canal to digest: its limbs are constructed to convey it where that prey is to be found, and no organ ever remains unemployed. The ant-bear, for instance, is not only armed with long claws on its fore-feet, in order to break into the nests of the white ant, but also with a prolonged cylindrical muzzle, in order to penetrate into them, with a small mouth and a long, threadlike tongue, covered with a glutinous slime, which it inserts into the white ants' nests and then withdraws covered with the insects that adhere to it: on the other hand it has no teeth, because it does not want them. Who can fail to see that the ant-bear's form stands in the same relation to the white ants, as an act of the will to its motive? The contradiction between the powerful fore-feet and long, strong, curved claws of the ant-bear and its complete lack of teeth, is at the same time so extraordinary, that if the earth ever undergoes a fresh transformation, the newly arising race of rational beings will find it an insoluble enigma, if white ants are unknown to them. The necks of birds, as of quadrupeds, are generally as long as their legs, to enable them to reach down to the ground where they pick up their food; but those of aquatic birds are often a good deal longer, because they have to fetch up their nourishment from under the water while swimming.[60] Moor-fowl have exceedingly long legs, to enable them to wade without drowning or wetting their bodies, and a correspondingly long neck and beak, this last being more or less strong, according to the things (reptiles, fishes or worms) which have to be crushed; and the intestines of these animals are invariably adapted likewise to this end. On the other hand, moor-fowl are provided neither with talons, like birds of prey, nor with web-feet, like ducks: for the *lex parsimoniæ naturæ* admits of no superfluous organ. Now, it is precisely this very law, added to the circumstance, that no organ required for its mode of life is ever wanting in any animal, and that all, even the most heterogeneous, harmonize together and are, as it were, calculated for a quite specially determined way of life, for the element in which the prey dwells, for the pursuit, the overcoming, the crushing and digesting of that prey, — all this, we say, proves, that the animal's structure has been determined by the mode of life by which the animal desired to find its sustenance, and not *vice versa*. It also proves, that the result is exactly the same as if a knowledge of that mode of life and of its outward conditions had preceded the structure, and as if therefore each animal had chosen its equipment before it assumed a body; just as a sportsman before starting chooses his

whole equipment, gun, powder, shot, pouch, hunting-knife and dress, according to the game he intends chasing. The latter does not take aim at the wild boar because he happens to have a rifle: he took the rifle with him and not a fowling-piece, because he intended to hunt the wild boar; and the ox does not butt because it happens to have horns: it has horns because it intends to butt. Now, to render this proof complete, we have the additional circumstance, that in many animals, during the time they are growing, the effort of the will to which a limb is destined to minister, manifests itself before the existence of the limb itself, its employment thus anticipating its existence. Young he-goats, rams, calves, for instance, butt with their bare polls before they have any horns; the young boar tries to gore on either side, before its tusks are fully developed which would respond to the intended effect, while on the other hand, it neglects to use the smaller teeth it already has in its mouth and with which it might really bite. Thus its mode of defending itself does not adapt itself to the existing weapons, but *vice versa*. This had already been noticed by Galenus[61] and by Lucretius[62] before him. All these circumstances give us complete certainty, that the will does not, as a supplementary thing proceeding from the intellect, employ those instruments which it may happen to find, or use the parts because just they and no others chance to be there; but that what is primary and original, is the endeavour to live in this particular way, to contend in this manner, an endeavour which manifests itself not only in the employment, but even in the existence of the weapon: so much so indeed, that the use of the weapon frequently precedes its existence, thus denoting that it is the weapon which arises out of the existence of the endeavour, not, conversely, the desire to use it out of the existence of the weapon. Aristotle expressed this long ago, when he said, with reference to insects armed with stings:[63] διὰ τὸ θυμὸν ἔχειν ὅπλον ἔχει (*quia iram habent, arma habent*), and further on, generally speaking:[64] Τὰ δ' ὄργανα πρὸς τὸ ἔργον ἡ φύσις ποιεῖ, ἀλλ' ού τὸ ἔργον πρὸς τὰ ὄργανα (*Natura enim instrumenta ad officium, non officium ad instrumenta accommodat*). From which it follows, that the structure of each animal is adapted to its will.

This truth forces itself upon thoughtful zoologists and zootomists with such cogency, that unless their mind is at the same time purified by a deeper philosophy, it may lead them into strange errors. Now this actually happened to a very eminent zoologist, the immortal De Lamarck, who has acquired everlasting fame by his discovery of the classification of animals

in *vertebrata* and *non-vertebrata*, so admirable in depth of view. For he quite seriously maintains and tries to prove[65] at length, that the shape of each animal species, the weapons peculiar to it, and its organs of every sort destined for outward use, were by no means present at the origin of that species, but have on the contrary *come into being* gradually *in the course of time* and through continued generation, in consequence of the exertions of the animal's will, evoked by the nature of its position and surroundings, through its own repeated efforts and the habits to which these gave rise. Aquatic birds and mammalia that swim, he says, have only become web-footed through stretching their toes asunder in swimming; moor-fowl acquired their long legs and necks by wading; horned cattle only gradually acquired horns because as they had no proper teeth for combating, they fought with their heads, and this combative propensity in course of time produced horns or antlers; the snail was originally, like other *mollusca*, without feelers; but out of the desire to feel the objects lying before it, these gradually arose; the whole feline species acquired claws only in course of time, from their desire to tear the flesh of their prey, and the moveable coverings of those claws, from the necessity of protecting them in walking without being prevented from using them when they wished; the giraffe, in the barren, grassless African deserts, being reduced for its food to the leaves of lofty trees, stretched out its neck and forelegs until at last it acquired its singular shape, with a height in front of twenty feet, and thus De Lamarck goes on describing a multitude of animal species as arising according to the same principle, in doing which he overlooks the obvious objection which may be made, that long before the organs necessary for its preservation could have been produced by means of such endeavours as these through countless generations, the whole species must have died out from the want of them. To such a degree may we be blinded by a hypothesis which has once laid hold of us! Nevertheless in this instance the hypothesis arose out of a very correct and profound view of Nature: it is an error of genius, which in spite of all the absurdity it contains, still does honour to its originator. The true part of it belongs to De Lamarck, as an investigator of Nature; he saw rightly that the primary element which has determined the animal's organisation, is the will of that animal itself. The false part must be laid to the account of the backward state of Metaphysics in France, where the views of Locke and of his feeble follower, Condillac, in fact still hold their ground and therefore bodies are held to be things in themselves, Time

and Space qualities of things in themselves; and where the great doctrine of the Ideal nature of Space and of Time and of all that is represented in them, which has been so extremely fertile in its results, has not yet penetrated. De Lamarck therefore could not conceive his construction of living beings otherwise than in Time, through succession. Errors of this sort, as well as the gross, absurd, atomic theory of the French and the edifying physico-theological considerations of the English, have been banished for ever from Germany by Kant's profound influence. So salutary was the effect produced by this great mind, even upon a nation capable of subsequently forsaking him to run after charlatanism and empty bombast. But the thought could never enter into De Lamarck's head, that the animal's will, as a thing in itself, might lie outside Time, and in this sense be prior to the animal itself. Therefore he assumes the animal to have first been without any clearly defined organs, but also without any clearly defined tendencies, and to have been equipped only with perception. Through this it learns to know the circumstances in which it has to live and from that knowledge arise its desires, *i.e.* its will, from which again spring its organs or definite embodiment; this last indeed with the help of generation and therefore in boundless Time. If De Lamarck had had the courage to carry out his theory fully, he ought to have assumed a primary animal[66] which, to be consistent, must have originally had neither shape nor organs, and then proceeded to transform itself according to climate and local conditions into myriads of animal shapes of all sorts, from the gnat to the elephant. — But this primary animal is in truth the *will to live*; as such however, it is metaphysical, not physical. Most certainly the shape and organisation of each animal species has been determined by its own will according to the circumstances in which it wished to live; not however as a thing physical in Time, but on the contrary as a thing metaphysical outside Time. The will did not proceed from the intellect, nor did the intellect exist, together with the animal, before the will made its appearance as a mere accident, a secondary, or rather tertiary, thing. It is on the contrary the will which is the *prius*, the thing in itself: its phenomenon (mere representation in the cognitive intellect and its forms of Space and Time) is the animal, fully equipped with all its organs which represent the will to live in those particular circumstances. Among these organs is the intellect also — knowledge itself — which, like the rest of those organs, is exactly adapted to the mode of life of each animal; whereas, according to De Lamarck, it is the will which

arises out of knowledge. Behold the countless varieties of animal shapes; how entirely is each of them the mere image of its volition, the evident expression of the strivings of the will which constitute its character! Their difference in shape is only the portrait of their difference in character. Ferocious animals, destined for combat and rapine, appear armed with formidable teeth and claws and strong muscles; their sight is adapted for great distances, especially when they have to mark their prey from a dizzy height, as is the case with eagles and condors. Timid animals, whose will it is to seek their safety in flight instead of contest, present themselves with light, nimble legs and sharp hearing in lieu of all weapons; a circumstance which has even necessitated a striking prolongation of the outer ear in the most timid of them all, the hare. The interior corresponds to the exterior: carnivorous animals have short intestines; herbivorous animals long ones, suited to a protracted assimilation. Vigorous respiration and rapid circulation of the blood, represented by appropriate organs, always accompany great muscular strength and irritability as their necessary conditions, and nowhere is contradiction possible. Each particular striving of the will presents itself in a particular modification of shape. The abode of the prey therefore has determined the shape of its pursuer: if that prey takes refuge in regions difficult of access, in remote hiding places, in night or darkness, the pursuer assumes the form best suited to those circumstances, and no shape is rejected as too grotesque by the will to live, in order to attain its ends. The cross-bill (*loxia curvirostra*) presents itself with this abnormal form of its organ of nutrition, in order to be able to extract the seeds out of the scales of the fir-cone. Moor-fowls appear equipped with extra long legs, extra long necks and extra long beaks, in short, the strangest shapes, in order to seek out reptiles in their marshes. Then we have the ant-bear with its body four feet long, its short legs, its strong claws, and its long, narrow, toothless muzzle provided with a threadlike, glutinous tongue for the purpose of digging out the white ants from their nests. The pelican goes fishing with a huge pouch under its beak in which to pack its fish, when caught. In order to surprise their prey while asleep in the night, owls fly out provided with enormous pupils which enable them to see in the dark, and with very soft feathers to make their flight noiseless and thus permit them to fall unawares upon their sleeping prey without awakening it by their movements. *Silurus*, *gymnotus* and *torpedo* bring a complete electric apparatus into the world with them, in order to stun their prey before they

can reach it; and also as a defence against *their own* pursuers. For wherever anything living breathed, there immediately came another to devour it,[67] and every animal is in a way designed and calculated throughout, down to the minutest detail, for the purpose of destroying some other animal. Ichneumons, for instance, among insects, lay their eggs in the bodies of certain caterpillars and similar *larvæ*, in which they bore holes with their stings, in order to ensure nourishment for their future brood. Now those kinds which feed on *larvæ* that crawl about freely, have short stings not more than about one-third of an inch long, whereas *pimpla manifestator*, which feeds upon *chelostoma maxillosa*, whose *larvæ* lie hidden in old trees at great depth and are not accessible to it, has a sting two inches long; and the sting of the *ichneumon strobillæ* which lays its eggs in *larvæ* dwelling in fir-cones, is nearly as long. With these stings they penetrate to the *larva* in which they bore a hole and deposit one egg, whose product subsequently devours this *larva*.[68] Just as clearly does the will to escape their enemies manifest itself in the defensive equipment of animals that are the objects of pursuit. Hedgehogs and porcupines raise up a forest of spears; armadillos, scaly ant-eaters and tortoises appear cased from head to foot in armour which is inaccessible to tooth, beak or claw; and so it is, on a smaller scale, with the whole class of *crustacea*. Others again seek protection by deceiving their pursuers rather than by resisting them physically: thus the sepia has provided itself with materials for surrounding itself with a dark cloud on the approach of danger. The sloth is deceptively like its moss-clad bough, and the frog its leaf; and many insects resemble their dwelling-places. The negro's louse is black;[69] so, to be sure, is our flea also; but the latter, in providing itself with an extremely powerful apparatus for making irregular jumps to a considerable distance, trusted to these for protection. — We can however make the anticipation in all these arrangements more intelligible to ourselves by the same anticipation which shows itself in the mechanical instincts of animals. Neither the young spider nor the ant-lion know the prey for which they lay traps, when they do it for the first time. And it is the same when they are on the defensive. According to Latreille, the insect *bombex* kills the *parnope* with its sting, although it neither eats it nor is attacked by it, simply because the *parnope* will lay its eggs in the *bombex's* nest, and by doing this will interfere with the development of its eggs; yet it does not know this. Anticipations of this kind once more

confirm the ideal nature of Time, which indeed always becomes manifest as soon as the will as thing in itself is in question. Not only with respect to the points here mentioned, but to many others besides, the mechanical instincts and physiological functions of animals serve to explain each other mutually, because the will without knowledge is the agent in both.

As the will has equipped itself with every organ and every weapon, offensive as well as defensive, so has it likewise provided itself in every animal shape with an *intellect*, as a means of preservation for the individual and the species. It was precisely in this account that the ancients called the intellect the ἡγεμονικόν, *i.e.* the guide and leader. Accordingly the intellect, being exclusively destined to serve the will, always exactly corresponds to it. Beasts of prey stood in greater need of intellect, and in fact have more intelligence, than herbivorous animals. The elephant certainly forms an exception, and so does even the horse to a certain extent; but the admirable intelligence of the elephant was necessary on account of the length of its life (200 years) and of the scantiness of its progeny, which obliged it to provide for a longer and surer preservation of the individual: and this moreover in countries teeming with the most rapacious, the strongest and the nimblest beasts of prey. The horse too has a longer life and a scantier progeny than the ruminants, and as it has neither horns, tusks, trunk, nor indeed any weapon save perhaps its hoofs, it needed greater intelligence and swiftness in order to elude pursuit. Monkeys needed their extraordinary intelligence, partly because of the length of their life, which even in the moderate-sized animal extends to fifty years; partly also because of their scanty progeny, which is limited to one at a time, but especially because of their *hands*, which, to be properly used, required the direction of an understanding. For monkeys depend upon their hands, not only for their defence by means of outer weapons such as sticks and stones, but also for their nourishment, this last necessitating a variety of artificial means and a social and artificial system of rapine in general, the passing from hand to hand of stolen fruit, the placing of sentinels, &c. &c. Add to this, that it is especially in their youth, before they have attained their full muscular development, that this intelligence is most prominent. In the *pongo* or ourang-outang for instance, the brain plays a far more important part and the understanding is much greater during its youth than at its maturity, when the muscular powers having attained full development, they take the place of the proportionately declining intellect. This holds good of all sorts of

monkeys, so that here therefore the intellect acts for a time vicariously for the yet undeveloped muscular strength. We find this process discussed at length in the "Résumé des Observations de Fr. Cuvier sur l'instinct et l'intelligence des animaux," par Flourens (1841), from which I have quoted the whole passage referring to this question in the second volume of my chief work, at the end of the thirty-first chapter, and this is my only reason for not repeating it here. On the whole, intelligence gradually increases from the rodents[70] to the ruminants, from the ruminants to the pachyderms, and from these again to the beasts of prey and finally to the *quadrumana*, and anatomy shows a gradual development of the brain in similar order which corresponds to this result of external observation. (According to Flourens and Fr. Cuvier.)[71] Among the reptiles, serpents are the most intelligent, for they may even be trained; this is so, because they are beasts of prey and propagate more slowly than the rest — especially the venomous ones. And here also, as with the physical weapons, we find the will everywhere as the *prius*; its equipment, the intellect, as the *posterius*. Beasts of prey do not hunt, nor do foxes thieve, because they have more intelligence; on the contrary, they have more intelligence, just as they have stronger teeth and claws too, because they wished to live by hunting and thieving. The fox even made up at once for his inferiority in muscular power and strength of teeth by the extraordinary subtility of his understanding. Our thesis is singularly illustrated by the case of the bird *dodo* or *dronte* (*didus ineptus*) on the island of Mauritius, whose species, it is well known, has died out, and which, as its Latin name denotes, was exceedingly stupid, and this explains its disappearance; so that here it seems indeed as if Nature had for once gone too far in her *lex parsimoniæ* and thereby in a sense brought forth an abortion in the species, as she so often does in the individual, which was unable to subsist, precisely because it was an abortion. If, on this occasion, anyone were to raise the question as to whether Nature ought not to have provided insects with at least sufficient intelligence to prevent them from flying into the flame of a candle, our answer would be: most certainly; only she did not know that men would make candles and light them, and *natura nihil agit frustra*. Insect intelligence is therefore only insufficient where the surroundings are artificial.[72]

Everywhere indeed intelligence depends in the first instance upon the cerebral system, and this stands in a necessary relation to the rest of the

organism; therefore cold-blooded animals are greatly inferior to warm-blooded ones, and invertebrate animals to *vertebrata*. But the organism is precisely nothing but the will become visible, to which, as that which is absolutely *prius*, everything constantly refers. The needs and aims of that will give in each phenomenon the rule for the means to be employed, and these means must harmonize with one another. Plants have no self-consciousness because they have no power of locomotion; for of what use would self-consciousness be to them unless it enabled them to seek what was salutary and flee what was noxious to them? And conversely, of what use could power of locomotion be to them, as they have no self-consciousness with which to guide it. The inseparable duality of Sensibility and Irritability does not yet appear therefore in the plant; they continue slumbering in the reproductive force which is their fundament, and in which alone the will here objectifies itself. The sun-flower, and every other plant, wills for light; but as yet their movement towards light is not separate from their apprehension of it, and both coincide with their growth. — Human understanding, which is so superior to that of all other beings, and is assisted by Reason (the faculty for non-perceptible representations, *i.e.* for conceptions; reflection, thinking faculty), is nevertheless only just proportionate, partly to Man's requirements, which greatly surpass those of animals and multiply to infinity; partly to his entire lack of all natural weapons and covering, and to his relatively weaker muscular strength, which is greatly inferior to that of monkeys of his own size;[73] lastly also, to the slowness with which his race multiplies and the length of his childhood and life, which demand secure preservation of the individual. All these great requirements had to be satisfied by means of intellectual powers, which, for this reason, predominate in him. But we find the intellect secondary and subordinate everywhere, and destined exclusively to serve the purposes of the will. As a rule too, it always remains true to its destiny and subservient to the will. How nevertheless, it frees itself in particular instances from this bondage through an abnormal preponderance of cerebral life, whereby purely objective cognition becomes possible which may be enhanced to genius, I have shown at length in the æsthetic part of my chief work.[74]

Now, after all these reflections upon the precise agreement between the will and the organisation of each animal, if we inspect a well-arranged osteological collection from this point of view, it will certainly seem to us

as if we saw one and the same being (De Lamarck's primary animal, or, more properly, *the will to live*) changing its shape according to circumstances, and thus producing all this multiplicity of forms out of the same number and arrangement of its bones, by prolonging and curtailing, strengthening and weakening them. This number and arrangement of the bones, which Geoffroy de St. Hilaire[75] called the anatomical element, continues, as he has thoroughly shown, in all essential points unchanged: it is a constant magnitude, something which is absolutely given beforehand, irrevocably fixed by an unfathomable necessity — an immutability which I should compare with the permanence of matter in all physical and chemical changes: but to this I shall soon return. Conjointly with this immutability of the anatomical element, we have the greatest susceptibility to modification, the greatest plasticity and flexibility of these same bones with reference to size, shape and adaptation to different purposes, all which we see determined by the will with primary strength and freedom according to the aims prescribed to it by external circumstances: it makes out of these materials whatever its necessity for the time being requires. If it desires to climb about in trees, it catches at the boughs at once with four hands, while it stretches the *ulva* and *radius* to an excessive length and immediately prolongs the *os coccygis* to a curly tail, a yard long, in order to hang by it to the boughs and swing itself from one branch to another. If, on the other hand, it desires to crawl in the mud as a crocodile, to swim as a seal, or to burrow as a mole, these same arm-bones are shortened till they are no longer recognisable; in the last case the *metacarpus* and *phalanges* are enlarged to disproportionately large shovel-paws, to the prejudice of the other bones. But if it wishes to fly through the air as a bat, not only are the *os humeri*, *radius* and *alnus* prolonged in an incredible manner, but the usually small and subordinate *carpus*, *metacarpus* and *phalanges digitorum* expand to an immense length, as in St. Anthony's vision, outmeasuring the length of the animal's body, in order to spread out the wing-membrane. If, in order to browse upon the tops of very tall African trees, it has, as a giraffe, placed itself upon extraordinarily high fore-legs, the same seven *vertebræ* of the neck, which never vary as to number and which, in the mole, were contracted so as to be no longer recognisable, are now prolonged to such a degree, that here, as everywhere else, the neck acquires the same length as the fore-legs, in order to enable the head to reach down to drinking-water. But where, as is the case when it appears as the elephant,

a long neck could not have borne the weight of the enormous, unwieldy head — a weight increased moreover by tusks a yard long — the neck remains short, as an exception, and a trunk is let down as an expedient, to lift up food and draw water from below and also to reach up to the tops of trees. In accordance with these transformations, we see in all of them the skull, the receptacle containing the understanding, at the same time proportionately expand, develop, curve itself, as the mode of procuring nourishment becomes more or less difficult and requires more or less intelligence; and the different degrees of the understanding manifest themselves clearly to the practised eye in the curves of the skull.

Now, in all this, that *anatomical element* we have mentioned above as fixed and invariable, certainly remains in so far an enigma, as it does not come within the teleological explanation, which only begins after the assumption of that element; since the intended organ might in many cases have been rendered equally suitable for its purpose even with a different number and disposition of bones. It is easy to understand, for instance, why the human skull should be formed out of eight bones: that is, to enable them to be drawn together by the fontanels during birth; but we do not see why a chicken which breaks through its egg-shell should necessarily have the same number of skull-bones. We must therefore assume this anatomical element to be based, partly on the unity and identity of the will to live in general, partly on the circumstance, that the archetypal forms of animals have proceeded one from the other,[76] wherefore the fundamental type of the whole race was preserved. It is this anatomical element which Aristotle means by his ἀναγκαία φύσις, and the mutability of its shapes according to different purposes he calls τὴν κατὰ λόγον φύσιν,[77] and explains by it how the material for upper incisors has been employed for horns in horned cattle. Quite rightly: since the only ruminants which have no horns, the camel and the musk-ox, have upper incisors, and these are wanting in all horned ruminants.

No other explanation or assumption enables us nearly as well to understand either the complete suitableness to purpose and to the external conditions of existence I have here shown in the skeleton, or the admirable harmony and fitness of internal mechanism in the structure of each animal, as the truth I have elsewhere firmly established: that the body of an animal is precisely nothing but the *will itself* of that animal brought to cerebral perception as representation — through the forms of Space, Time and

Causality — in other words, the mere visibility, objectivity of Will. For, if this is once pre-supposed, everything in and belonging to that body must conspire towards the final end: the life of this animal. Nothing superfluous, nothing deficient, nothing inappropriate, nothing insufficient or incomplete of its kind, can therefore be found in it; on the contrary, all that is required must be there, and just in the proportion needed, never more. For here artist, work and materials are one and the same. Each organism is therefore a consummate master-piece of exceeding perfection. Here the will did not first cherish the intention, first recognise the end and then adapt the means to it and conquer the material; its willing was rather immediately the aim and immediately the attainment of that aim; no foreign appliances needing to be overcome were wanted — willing, doing and attaining were here one and the same. Thus the organism presents itself as a miracle which admits of no comparison with any work of human artifice wrought by the lamplight of knowledge.[78]

Our admiration for the consummate perfection and fitness for their ends in all the works of Nature, is at the bottom based upon our viewing them in the same light as we do our own works. In these, in the first place, the will to do the work and the work are two different things; then again two other things lie between these two: firstly, the medium of representation, which, taken by itself, is foreign to the will, through which the will must pass before it realizes itself here; and secondly the material foreign to the will here at work, on which a form foreign to it has to be forced, which it resists, because the material already belongs to another will, that is to say, to its own nature, its *forma substantialis*, the (Platonic) idea, expressed by it: therefore this material has first to be overcome, and however deeply the artificial form may have penetrated, will always continue inwardly resisting. It is quite a different thing with Nature's works, which are not, like our own, indirect, but on the contrary, direct manifestations of the will. Here the will acts in its primordial nature, that is, unconsciously. No mediating representation here separates the will and the work: they are one. And even the material is one with them: for matter is the mere visibility of the will. Therefore here we find Matter completely permeated by Form; or, better still, they are of quite the same origin, only existing mutually one for the other; and in so far they are one. That we separate them in works of Nature as well as in works of Art, is a mere abstraction. Pure Matter, absolutely without Form or quality, which we think as the material of a

product of Nature, is merely an *ens rationis* and cannot enter into any experience: whereas the material of a work of Art is empirical Matter, consequently already has a Form. The [distinctive] character of Nature's products is the identity of form and substance; that of products of Art the diversity of these two.[79] It is because Matter is the mere visibility of Form in Nature's products, that, even empirically, we see Form appear as a mere production of Matter, bursting forth from its inside in crystallisation, in vegetable and animal *generatio æquivoca*, which last cannot be doubted, at any rate in the *epizoa*.[80] — For this reason we may even assume that nowhere, either on any planet or satellite, will Matter come to a state of endless repose, but rather that its inherent forces (*i.e.* the will, whose mere visibility it is) will always put an end again to the repose which has commenced, always awaking again from their sleep, to resume their activity as mechanical, physical, chemical, organic forces; since at all times they only wait for the opportunity to do so.

But if we want to understand Nature's proceeding, we must not try to do it by comparing her works with our own. The real essence of every animal form, is an act of the will outside representation, consequently outside its forms of Space and Time also; which act, just on that account, knows neither sequence nor juxtaposition, but has, on the contrary, the most indivisible unity. But when our cerebral perception comprehends that form, and still more when its inside is dissected by the anatomical knife, then that which originally and in itself was foreign to knowledge and its laws, is brought under the light of knowledge; but then also, it has to present itself in conformity with the laws and forms of knowledge. The original unity and indivisibility of that act of the will, of that truly metaphysical being, then appears divided into parts lying side by side and functions following one upon another, which all nevertheless present themselves as connected together in closest relationship one to another for mutual help and support, as means and ends one to the other. The understanding, in thus apprehending these things, now perceives the original unity re-establishing itself out of a multiplicity which its own form of knowledge had first brought about, and involuntarily taking for granted that its own way of perceiving this is the way in which this animal form comes into being, it is now struck with admiration for the profound wisdom with which those parts are arranged, those functions combined. This is the meaning of Kant's great doctrine, that Teleology is brought into Nature by our own understanding,

which accordingly wonders at a miracle of its own creation.[81] If I may use a trivial simile to elucidate so sublime a matter, this astonishment very much resembles that of our understanding when it discovers that all multiples of 9, when their single figures are added together, give as their product either the number 9 or one whose single figures again make 9; yet it is that very understanding itself which has prepared for itself this surprise in the decimal system. According to the Physico-theological argument, the actual existence of the world has been preceded by its existence in an intellect: if the world is designed for an end, it must have existed as representation before it came into being. Now I say, on the contrary, in Kant's sense: if the world is to be representation, it must present itself as designed for an end; and this only takes place in an intellect.

It undoubtedly follows from my doctrine, that every being is its own work. Nature, which is incapable of falsehood and is as *naïve* as genius, asserts the same thing downright; since each being merely kindles the spark of life at another exactly similar being, and then makes itself before our eyes, taking the materials for this from outside, form and movement from its own self: this process we call growth and development. Thus, even empirically, each being stands before us as its own work. But Nature's language is not understood because it is too simple.

PHYSIOLOGY OF PLANTS.

The corroborations I am now about to bring forward of the phenomenon of the will in plants, proceed chiefly from French sources, from a nation whose tendencies are decidedly empirical and which is reluctant to go a step beyond what is immediately given. The informant moreover is Cuvier, whose rigid adherence to the purely empirical gave rise to the famous dispute between him and Geoffroy de St. Hilaire. So we must not be astonished if the language we meet with here is less decided than in the preceding German corroborations and if we find each concession made with cautious reserve.

In his "Histoire des Progrès des Sciences Naturelles depuis 1789 jusqu'á ce jour,"[82] Cuvier says: "Plants have certain apparently spontaneous movements, which they show under certain circumstances and which at times so closely resemble those of animals, that a sort of feeling and *will* might almost be attributed to plants on this account, especially by those who think they can perceive something of the same kind in the movements of the *inward* parts of animals. Thus the tops of trees always have a vertical tendency, excepting when they incline towards the light. Their roots seek out good earth and moisture and, in order to attain these, deviate from the straight course. Yet these different tendencies cannot be explained by the influence of external causes, unless we also assume the existence of an inner natural disposition, susceptible of being roused, which differs from the mere mechanical force in inorganic bodies.... Decandolle made some remarkable experiments that proved to him the existence of a sort of habit in plants which may be overcome by artificial light, but only after a certain time. Plants that had been shut up in a cellar which was continually lit by lamps, did not on this account leave off closing in the evening and opening again in the morning for several days. And there are other habits besides which plants are able to adopt and to abandon. Flowers that habitually close in wet weather, finish by remaining open if the wet weather lasts too long. When M. Desfontaines took a sensitive plant with him in his carriage, the jolting movement at first caused it to contract, but at last it expanded again as when in complete repose. Therefore even in these cases, light, moisture, &c., &c., only act in virtue of an inner disposition, which may be neutralized or modified by the continuation of that very activity itself; and

the vital energy of plants, like that of animals, is subject to fatigue and exhaustion. The *hedysarum gyrans* is singularly characterized by the movements of its leaves which continue day and night without needing any sort of stimulus. Surely, if any phenomenon can cause illusion and remind us of the voluntary movements of animals, it is this. Broussonet, Silvestre, Cels and Halle have fully described it, and have shown that the plant's action depends entirely upon its own healthy condition."

Again, in the third volume of the same work, p. 166 (1828), Cuvier says: "M. Dutrochet adds some physiological considerations to which his own experiments had led him, and which in his opinion prove that the movements of plants are *spontaneous*, *i.e.* that they depend upon an inner principle which immediately receives the influence of outer agencies. As he is however reluctant to admit that plants have feeling, he makes use of the word '*nervimotilité*.'" — Here I must observe, that when we come to examine it closely, what we think to ourselves in the conception of *spontaneity*, is in the end always the same thing as manifestation of will, with which spontaneity would therefore be simply synonymous. The only difference between them consists in the conception of spontaneity being derived from outer perception, while that of manifestation of will is drawn from our own consciousness. — I find a remarkable instance of the impetuous violence of this spontaneity, even in plants, in the following communication contained in the "Cheltenham Examiner:"[83] "Last Thursday four enormous mushrooms performed a heroic feat of a new kind, in one of our most crowded streets, by lifting up a huge block of stone in their strenuous effort to make their way into the visible world."

In the "Mém. de l'Acad. d. Sciences de l'année" (1821), Cuvier says[84]:— "For centuries botanists have been searching for the reason why in a seed which is germinating the root invariably grows downwards, while the stalk as invariably grows upwards, no matter what be the position in which the seed is placed. M. Dutrochet put some seeds into holes bored in the bottom of a vessel filled with damp mould, which he hung up to a beam in his room. Now, in this case, the stem might have been expected to grow downwards. Not at all: the roots found their way to the air below, and the stems were prolonged so as to traverse the damp mould until they reached its upper surface. According to M. Dutrochet, the direction in which plants grow, is determined by an inner principle and not at all by the attraction of the bodies towards which they direct themselves. A mistletoe seed that was

fastened to the point of a perfectly moveable needle fixed on a peg, with a small plank placed near it, was induced to germinate. It soon began to send out shoots towards the plank, which it reached in five days without having communicated the slightest movement to the needle. The stems of onions and leeks with their bulbs, deposited in dark places, grow upwards, although more slowly than in light ones; they grow upwards even if placed in water: a fact which suffices to prove that neither light nor moisture determines the direction of their growth." — Still C. H. Schultz asserts[85] that he made seeds germinate in a dark box with holes bored in the bottom, and succeeded in inducing the plants to grow upside down, by means of a mirror fastened to the box, which reflected the sunlight.

In the "Dictionnaire des Sciences Naturelles" (article *Animal*) we find: "If, on the one hand, animals show avidity in their search after nourishment as well as power of discrimination in the selection of it, roots of plants may, on the other hand, be observed to direct themselves towards the side where the soil contains most nourishment, nay, even to seek out the smallest crevices in rocks which may contain any food. If we twist a bough so as to make the upper surface of its leaves the under one, these leaves even will twist their stems in order to regain the position best suited for the exercise of their functions (*i.e.* so as to have the smooth side uppermost). Is it quite certain that this takes place unconsciously?"

F. J. Meyen has devoted a chapter, entitled "Of the movements and sensations of plants," to a full investigation of the subject now before us. In this he says[86]: "Not unfrequently potatoes, stored in deep, dark cellars, may be observed towards summer to shoot forth stems which invariably grow in the direction of the chinks through which the light comes into the cellar, and to continue thus growing until they at last reach the aperture which receives the light directly. In such cases potato-stalks have been known to reach a length of twenty feet; whereas under ordinary circumstances, even such as are most favourable to the growth of the potato, the stalk is seldom longer than from three to four feet. It is interesting to watch closely the course taken by a potato-stalk thus growing in darkness, in its endeavours to reach the light. It tries to do so by the shortest road, but not being firm enough to grow straight across through the air without support, it lets itself drop on to the floor, and thus creeps along the ground till it reaches the nearest wall, up which it then climbs." Even this botanist too is led by his facts to the following assertion (p. 576): "On observing the freedom of movement of

oscillatoria and other inferior plants, we may perhaps have no alternative but to attribute a species of *will* to these beings."

Creepers bear distinct evidence as to manifestation of will in plants; for, when they find no support near enough for their tendrils to cling to, they invariably direct their growth towards the shadiest place, or even towards a piece of dark-coloured paper, wherever it may be placed; whereas they avoid glass, on account of its glitter. In the "Philosophical Transactions" of 1812, Th. Andrew Knight relates some very pleasing experiments on this subject (especially with *ampelopsis quinquefolia*,)[87] although he strives hard to explain the matter mechanically, and will not admit that it is a manifestation of will. I appeal to his experiments, not to the conclusions he draws from them. A good test might be, to plant several free creepers in a circle round a tree-trunk and to observe whether they all crept towards the trunk centripetally. On the 6th Nov. 1843, Dutrochet read a treatise on this subject in the "Acad. de Sciences" called "Sur les Mouvements Révolutifs spontanés chez les Végétaux," which, notwithstanding its great length, is well worth reading, and is published among the "Comptes rendus des Séances de l'Académie des Sciences" for Nov. 1843. The result is, that in *pisum sativum* (green pea), in *bryonia alba* (wild bryony) and in *cucumis sativus* (cucumber) the stems of those leaves which bear the tendrils, describe a very slow circular movement in the air, the time in which they complete an ellipsis varying from one to three hours according to temperature. By this movement they seek at random for solid bodies round which, when found, they twine their tendrils; these then support the plant, it being unable to stand by itself without help. That is, they do the same thing as the eyeless caterpillar, which when seeking a leaf describes circles in the air with the upper part of its body. Dutrochet contributes a good deal of information too concerning other movements in plants in this treatise: for instance, that *stylidium graminifolium* in New Holland, has a column in the middle of its *corolla* which bears the anthers and *stigma* and alternately folds up and unfolds again. What Treviranus adduces is to the same effect:[88] "In *parnassia palustris* and in *ruta graveolens*, the stamina incline one after the other, in *saxifraga tridactylites* in pairs, towards the stigma, and erect themselves again in the same order." — Shortly before however, we read in Treviranus with reference to this subject: "Of all apparently voluntary movements of plants, the direction of their boughs and of the upper surface of their leaves towards the light and towards moist heat, and the twining

movements of creepers round their supports, are the most universal. In this last phenomenon especially there is something which resembles animal movements. While growing, creepers, it is true, if left to themselves, describe circles with their tips and by this means reach an object near at hand. But it is no merely mechanical cause that induces them to adapt their growth to the form of the object they have thus reached. The *cuscuta* does not twine round every kind of support: for instance, limbs of animals, dead vegetable matter, metals and inorganic substances are not used for this purpose, but only living plants, and not even all kinds — not mosses, for instance — only those from which it can extract nourishment by its *papillæ*; and these attract it from a considerable distance."[89] The following special observation, communicated to the "Farmer's Magazine," and reproduced by the "Times" (13th July 1848) under the title "Vegetable Instinct," is however still more to the point: "If a basin of water be placed within six inches of a young pumpkin-stalk, or of a stem of the large garden pea, no matter on what side, the stalk will approach the basin during the night and it will be found next morning with one of its leaves floating on the water. This experiment may be renewed every night till the plant begins to fructify. — Even if its position be changed every day, a stick fixed upright within six inches of a young convolvulus is sure to be found by the plant. If, after having wound itself for a certain distance round the stick, it is unwound and wound round again in the opposite direction, it will return to its original position or lose its life in the endeavour to do so. Nevertheless, if two such plants grow close to one another without having any stick near enough for them to cling to it, one of them will change the direction of its winding and they will twine round each other. Duhamel placed some Italian beans in a cylinder filled with moist earth; after a little while they began to germinate and naturally sent their *plumula* upwards in the direction of the light and their *radicula* downwards into the mould. After a few days the cylinder was turned round to the extent of a quarter of its circumference and the same process was repeated until it had been turned completely round. The beans were then removed from the earth, when it was found that both *plumula* and *radicula* had twisted at each turn that had been given, in order to adapt themselves to it, the one endeavouring to rise perpendicularly, the other to descend, so that they had formed a complete spiral. Yet, notwithstanding this natural tendency to descend, when the soil below is too dry, roots will

grow upwards in order to reach any moist substance which may be lying higher than themselves."

In Froriep's "Memoranda" for 1833 (No. 832) there is a short article upon the locomotivity of plants: in poor soil, where good mould lies near at hand, many plants will send out a shoot into the good mould; after a time the original plant then withers, but the offshoot prospers and itself becomes the plant. By means of this process, a plant has been known to climb down from a wall.

In the same periodical (1835, No. 981) is to be found a communication from Professor Daubeny, of Oxford (taken from the "Edinburgh New Philosophical Journal," April-July, 1835), in which he shows with certainty, by means of new and very careful experiments, that roots of plants have, at any rate to a certain degree, the power to make choice from those substances in the soil which present themselves to their surface.[90]

Finally I will not omit to observe, that even so early an authority as Plato[91] had attributed desires, ἐπιθυμίας, *i.e. will*, to plants. In my chief work,[92] however, I have entered into the doctrines of the Ancients on this point, and the chapter there which treats of this subject may on the whole serve to complete the present one.

The reluctance and reserve with which we see the authors here quoted make up their minds to acknowledge the will, which nevertheless undoubtedly manifests itself in plants, comes from their being still hampered by the old opinion, that consciousness is a requisite and condition of the will: now it is evident that plants have no consciousness. The thought never entered into the heads of these naturalists, that the will might be the *prius* and therefore independent of the intellect, with which, as the *posterius*, consciousness first makes its appearance. As for knowledge or representation, plants have something merely analogous to it, a mere substitute for it; whereas they really have the will itself quite directly: for, as the thing in itself, it is the substratum of their phenomenal being as well as of every other. Taking a realistic view, starting accordingly from the objective, the matter might even be stated as follows: That which lives and moves in plant-nature and in the animal organism, when it has gradually enhanced itself in the scale of beings sufficiently for the light of knowledge to fall directly upon it, presents itself in this newly arising consciousness as *will*, and is here more immediately, consequently better, known than anywhere else. This knowledge therefore must supply the key for the

comprehension of all that is lower in the scale. For in this knowledge the thing in itself is no longer veiled by any other form than that of the most immediate apprehension. It is this immediate apprehension of one's own volition which has been called the inner sense. In itself the will is without apprehension, and remains so in the inorganic and vegetable kingdoms. Just as the world would remain in darkness, in spite of the sun, if there were no bodies to reflect its light; or as the mere vibration of a string can never become a sound without air or even without some sort of sounding-board: so likewise does the will first become conscious of itself when knowledge is added to it. Knowledge is, as it were, the sounding-board of the will, and consciousness the tone it produces. This becoming conscious of itself on the part of the will, was attributed to a supposed inner sense, because it is the first and most direct knowledge we have. The various emotions of our own will can alone be the object of this inner sense; for the process of representation itself cannot over again be perceived, but, at the very utmost, only be once more brought to consciousness in rational reflection, that second power of representing: that is, *in abstracto*. Therefore also, simple representation (intuition) is to thinking proper — that is, to knowing by means of abstract conceptions — what willing in itself is to becoming aware of that willing, *i.e.* to consciousness. For this reason, a perfectly clear and distinct consciousness, not only of our own existence but also of the existence of others, only arises with the advent of Reason (the faculty for conceptions), which raises Man as far above the brute, as the merely intuitive faculty of representation raises the brute above the plant. Now beings which, like plants, have no faculty for representation, are called unconscious, and we conceive this condition as only slightly differing from non-existence; since the only existence such beings have, is in the consciousness of others, as the representation of those others. They are nevertheless not wanting in what is primary in existence, the will, but only in what is secondary; still, what is primary — and this is after all the existence of the thing in itself — appears to us, without that secondary element, to pass over into nullity. We are unable directly and clearly to distinguish unconscious existence from non-existence, although we have our own experience of it in deep sleep.

Bearing in mind, according to the contents of the last chapter, that the faculty of knowing, like every other organ, has only arisen for the purpose of self-preservation, and that it therefore stands in a precise relation,

admitting of countless gradations, to the requirements of each animal species; we shall understand that plants, having so very much fewer requirements than animals, no longer need any knowledge at all. On this account precisely, as I have often said, knowledge is the true characteristic which denotes the limits of animality, because of the movement induced by motives which it conditions. Where animal life ceases, there knowledge proper, with whose essence our own experience has made us familiar, disappears; and henceforth analogy is our only way of making that which mediates between the influence of the outer world and the movements of beings intelligible to us. The will, on the other hand, which we have recognised as being the basis and kernel of every existing thing, remains one and the same at all times and in all places. Now, in the lower degree occupied by plant-life and by the vegetative life of animal organisms, it is the *stimulus* which takes the place of knowledge as a means of determining the individual manifestations of this omnipresent will and as a mediator between the outer world and the changes of such a being; finally, in inorganic Nature, it is *physical agency in general*; and when, as here, observation takes place from a higher to a lower degree, both stimulus and physical agency present themselves as substitutes for knowledge, therefore as mere analogues to it. Plants cannot properly be said to perceive light and the sun; yet we see them sensitive in various ways to the presence or absence of both. We see them incline and turn towards the light; and though this movement no doubt generally coincides with their growth, just as the moon's rotation on its axis coincides with its movement round the earth, it nevertheless exists, as well as that of the moon, and the direction of that growth is determined and systematically modified by light, just as an action is determined by a motive, and as the direction of the growth of creeping and clinging plants is determined by the shape and position of the supports they may chance to find. Thus because plants on the whole, still have wants, though not such wants as demand the luxury of a sensorium and an intellect, something analogous has to take the place of these, in order to enable the will to lay hold of, if not to seek out, the satisfactions which offer themselves to it. Now, this analogous substitute is susceptibility for stimuli, and I would express the difference between knowledge and this susceptibility as follows: in knowledge, the motive which presents itself as representation and the act of volition which follows from it, *remain distinctly separate one from the other*, this separation moreover being the

more distinct, the greater the perfection of the intellect; — whereas, in mere susceptibility for stimuli, the feeling of the stimulus can no longer be distinguished from the volition it occasions, and they coalesce. In inorganic nature finally, even susceptibility for stimuli, the analogy of which to knowledge is unmistakable, ceases, but the diversity of reaction of each body upon divers kinds of action remains; now, when the matter is considered, as we are doing, in the descending scale, this reaction still presents itself, even here, as a substitute for knowledge. If a body reacts differently, it must have been acted upon differently and that action must have roused a different sensation in it, which with all its dullness has nevertheless a distant analogy to knowledge. Thus when water that is shut up finds an outlet of which it eagerly avails itself, rushing vehemently in that direction, it certainly does not recognise that outlet any more than the acid perceives the alkali approaching it which will induce it to abandon its combination with a metal, or than the strip of paper perceives the amber which attracts it after being rubbed; yet we cannot help admitting that what brings about such sudden changes in all these bodies, bears a certain resemblance to that which takes place within us, when an unexpected motive presents itself. In former times I have availed myself of such considerations as these in order to point out the will in all things; I now employ them to indicate the sphere to which knowledge presents itself as belonging, when considered, not as is usual from the inside, but realistically, from a standpoint outside itself, as if it were something foreign: that is, when we gain the objective point of view for it, which is so extremely important in order to complete the subjective one.[93] We find that knowledge then presents itself as the *mediator of motives*, *i.e.* of the action of causality upon beings endowed with intellect — in other words, as that which receives the changes from outside upon which those in the inside must follow, as that which acts as mediator between both. Now upon this narrow line hovers *the world as representation* — that is to say, the whole corporeal world, stretched out in Space and Time, which *as such* can never exist anywhere but in the brain any more than dreams, which, as long as they last, exist in the same way. What the intellect does for animals and for man, as the mediator of motives, susceptibility for stimuli does for plants, and susceptibility for every sort of cause for inorganic bodies: and strictly speaking, all this differs merely in degree. For, exclusively as a consequence of this susceptibility to outward impressions having enhanced

itself in animals proportionately to their requirements till it has reached the point where a nervous system and a brain become necessary, does consciousness arise as a function of that brain, and in it the objective world, whose forms (Time, Space, Causality) are the way in which that function is performed. Therefore we find the intellect originally laid out entirely with a view to subjectivity, destined merely to serve the purposes of the will, consequently as something quite secondary and subordinate; nay, in a sense, as something which appears only *per accidens*; as a condition of the action of mere motives, instead of stimuli, which has become necessary in the higher degree of animal existence. The image of the world in Space and Time, which thus arises, is only the map[94] on which the motives present themselves as ends. It also conditions the spacial and causal connection in which the objects perceived stand to one another; nevertheless it is only the mediating link between the motive and the act of volition. Now, to take such an image as this of the world, arising in this manner, accidentally, in the intellect, *i.e.* in the cerebral function of animal beings, through the means to their ends being represented and the path of these ephemera on their planet being thus illumined — to take this image, we say, this mere cerebral phenomenon, for the true, ultimate essence of things (thing in itself), to take the concatenation of its parts for the absolute order of the Universe (relations between things in themselves), and to assume all this to exist even independently of the brain, would indeed be a leap! Here in fact, an assumption such as this must appear to us as the height of rashness and presumption; yet it is the foundation upon which all the systems of pre-Kantian *dogmatism* have been built up; for it is tacitly pre-supposed in all their Ontology, Cosmology and Theology, as well as in the *æternæ veritates* to which they appeal. But that leap had always been made tacitly and unconsciously, and it is precisely Kant's immortal achievement, to have brought it to our consciousness.

By our present realistic way of considering the matter therefore, we unexpectedly gain the *objective stand-point* for Kant's great discoveries; and, by the road of empirico-physiological contemplation, we arrive at the point whence his transcendental-critical view starts. For Kant's view takes the subjective for its standpoint and considers consciousness as given. But from consciousness itself and its law and order, given *à priori*, that view arrives at the conclusion, that all which appears in that consciousness can be nothing more than mere phenomenon. From our realistic, exterior

standpoint, on the contrary, which assumes the *objective* — all that exists in Nature — to be absolutely given, we see what the intellect is, as to its aim and origin, and to which class of phenomena it belongs, and we recognise (so far *à priori*) that it *must* be limited to mere phenomena. We see too, that what presents itself in the intellect can at all times only be conditioned — chiefly *subjectively* — that is, can, together with the order of the nexus of its parts, only be a *mundus phenomenon*, which is likewise subjectively conditioned; but that it can never be a knowledge of things as they may be in themselves, or as they may be connected in themselves. For, in the nexus of Nature, we have found the faculty of knowing as a conditioned faculty, whose assertions, precisely on that account, cannot claim unconditioned validity. To anyone who has studied and understood the Critique of Pure Reason — to which our standpoint is essentially foreign — it must nevertheless still appear as if Nature had intended the intellect for a puzzle-glass to mislead us and were playing at hide-and-seek with us. But by our realistic objective road, *i.e.* by starting from the objective world as given, we have now come to the very same result at which Kant had arrived by the idealistic, subjective road, *i.e.* by examining the intellect itself and the way in which it constitutes consciousness. We now see that the world as representation hovers on the narrow line between the external cause (motive) and the effect evoked (act of the will), in beings having knowledge (animals), in which beings for the first time there occurs a distinct separation between motive and voluntary act. *Ita res accendent lumina rebus.* It is only when it is reached by two quite opposite roads, that the great result attained by Kant is distinctly seen; and when light is thus thrown upon it from both sides, his whole meaning becomes clear. Our objective standpoint is realistic and therefore conditioned, so far as, in taking for granted the existence of beings in Nature, it abstracts from the fact that their objective existence postulates an intellect, which contains them as its representation; but Kant's subjective and idealistic standpoint is likewise conditioned, inasmuch as he starts from the intelligence, which itself, however, presupposes Nature, in consequence of whose development as far as animal life that intelligence is for the first time enabled to make its appearance. — Keeping steadily to this realistic, objective standpoint of ours, we may also define Kant's theory as follows: After Locke, in order to know things in themselves, had abstracted the share of sensuous functions — called by him secondary qualities — from things as they appear, Kant

with infinitely greater depth deducted from them the incomparably larger share of the cerebral function, which includes precisely what Locke calls primary qualities. But all I have done here has been to show why all this must necessarily be as it is, by indicating the place occupied by the intellect in the nexus of Nature, when we start realistically from the objective as given, but, in doing so, take the only thing of which we are quite directly conscious, the *will* — that true ποῦ στῶ of Metaphysics — for our support, as being what is primarily real, everything else being merely its phenomenon. What now follows serves to complete this.

I have mentioned already, that where knowledge takes place, the motive which appears as representation and the act of volition resulting from it, remain *the more clearly separated one from the other*, the more perfect the intellect; that is, the higher we ascend in the scale of beings. This calls for fuller explanation. As long as the will's activity is roused by stimuli alone, and no representation as yet takes place — that is, in plants — there is no separation at all between the receiving of impressions and the being determined by them. In the lowest order of animal intelligence, such as we find it in *radiaria*, *acalepha*, *acephala*, &c., the difference is still small; a feeling of hunger, a watchfulness roused by this, an apprehending and snapping at their prey, still constitute the whole content of their consciousness; nevertheless this is the first twilight of the dawning world as representation, the background of which — that is to say, everything excepting the motive which acts each time — still remains shrouded in impenetrable darkness. Here moreover the organs of the senses are correspondingly imperfect and incomplete, having exceedingly few data for perception to bring to an understanding yet in embryo. Nevertheless wherever there is sensibility, it is always accompanied by understanding, *i.e.* with the faculty for referring effects experienced to external causes; without this, sensibility would be superfluous and a mere source of aimless suffering. The higher we ascend in the scale of animals, the greater number and perfection of the senses we find, till at last we have all five; these are found in a small number of invertebrate animals, but they only become universal in the *vertebrata*. The brain and its function, the understanding, develop proportionately, and the object now gradually presents itself more and more distinctly and completely and even already in connection with other objects; because the service of the will requires apprehension of the mutual relations of objects. By this the world of representation acquires

some extent and background. Still that apprehension never goes beyond what is required for the will's service: the apprehending and the being roused to reaction by what is apprehended, are not clearly held asunder: the object is only perceived in as much as it is a motive. Even the more sagacious animals only see in objects what concerns themselves, what has reference to their will or, at the utmost, what may have reference to it in future: of this last we have an instance in cats, who take pains to acquire an accurate knowledge of localities, and in foxes, who endeavour to find hiding-places for their future prey. But they are insensible towards everything else; no animal has perhaps ever yet seen the starry sky: my dog started in terror when for the first time he accidentally caught sight of the sun. A first faint sign of a disinterested perception of their surroundings may at times be observed in the most intelligent animals, especially when they have been trained by taming. Dogs go so far as to stare at things; we may often see them sit down at the window and attentively watch all that passes. Monkeys look about them at times, as if trying to make up their mind about their surroundings. It is in Man that the separation between motive and action, between representation and will, first becomes quite distinct. But this does not immediately put an end to the subservience of the intellect to the will. Ordinary human beings after all only comprehend quite clearly that which, in some way or other, refers directly or indirectly to their own selves (has an interest for them); with respect to everything else, their understanding continues to be unconquerably inert; the rest therefore remains in the back-ground and does not come into consciousness under the radiant light of complete distinctness. Philosophical astonishment and artistic emotion occasioned by the contemplation of phenomena, remain eternally foreign to them, whatever they may do; for at the bottom, everything appears to them to be a matter of course. Complete liberation and separation of the intellect from the will and its bondage is the prerogative of genius, as I have fully shown in the æsthetic part of my chief work. Genius is objectivity. The pure objectivity and distinctness with which things present themselves in intuitive perception — that fundamental and most substantial source of knowledge — actually stands every moment in inverse proportion to the interest which the will has in those things; and knowing without willing is the condition, not to say the essence, of all gifts of æsthetic intelligence. Why does an ordinary artist produce so bad a painting of yonder landscape, notwithstanding all the pains he has taken?

Because he sees it so. And why does he see so little beauty in it? Because his intellect has not freed itself sufficiently from his will. The degrees of this separation give rise to great intellectual distinctions between men; for the more knowledge has freed itself from the will, the purer, consequently the more objective and correct, it is; just as that fruit is best, which has no after-taste of the soil on which it has grown.

This relation, as important as it is interesting, deserves surely to be made still clearer by a retrospective view of the whole scale of beings, and by recalling the gradual transition from absolute subjectivity to the highest degrees of objectivity in the intellect. Inorganic Nature namely, is absolutely subjective, no trace whatever of consciousness of an outer world being found in it. Stones, boulders, ice-blocks, even when they fall upon one another, or knock or rub against one another, have no consciousness of each other and of an outer world. Still even these are susceptible to external influence, which causes their position and movement to change and may therefore be considered as a first step towards consciousness. Now, although plants also have no consciousness of the outer world, and although the mere analogue of a consciousness which exists in them must, on the contrary, be conceived as a dull self-enjoyment; yet we see that they all seek light, and that many of them turn their flowers or leaves daily towards the sun, while creepers find their way to supports with which they are not in contact; and finally we see individual kinds of plants show even a sort of irritability. Unquestionably therefore, there is a connection and relation between their movements and surroundings, even those with which they are not in immediate contact; and this connection we must accordingly recognise as a faint analogue to perception. With animal life first appears decided perception — that is, consciousness of other things, as opposed to that clear consciousness of ourselves to which that consciousness of other things first gives rise. This constitutes precisely the true character of animal-nature, as opposed to plant-nature. In the lowest animals, consciousness of the outer world is very limited and dim: each increasing degree of understanding extends it and makes it clearer, and this gradual increase of the understanding again adapts itself to the gradually increasing requirements of the animal, and thus the process continues through the whole long ascending scale of the animal series up to Man, in whom consciousness of the outer world reaches its acme, and in whom the world accordingly presents itself more distinctly and completely than in any other

being. Still, even here, there are innumerable degrees in the clearness of consciousness, from the dullest blockhead to genius. Even in normal heads there still remains a considerable tinge of subjectivity in their objective perception of external objects, knowledge still bearing throughout the character of existing merely for the ends of the will. The more eminent the head, the less prominent is this character, and the more purely objective does the representation of the outer world become; till in genius finally it attains completely objectivity, by which the Platonic ideas detach themselves from the individual things, because the mind which comprehends them enhances itself to the pure subject of knowledge. Now, as perception is the basis of all knowledge, all thinking and all insight must be influenced by this fundamental difference in the quality of it, from which arises that complete difference between the ordinary and the superior mind in their whole way of viewing things, which may be noticed on all occasions. From this also proceeds the dull gravity, nearly resembling that of animals, which characterizes common-place heads whose knowledge is acquired solely for the benefit of the will, as opposed to the constant play of exuberant intellect which brightens the consciousness of the superior mind. The consideration of the two extremes in the great scale which we have here exhibited, seems to have given rise to the German hyperbolical expression "*Block*" (*Klotz*), as applied to human beings, and to the English "blockhead."

But another different consequence of the clear separation of the will from the intellect — therefore of the motive from the action, — which first appears in the human race, is the deceptive illusion of freedom in our individual actions. Where, as in inorganic nature, causes, or, as in the vegetable kingdom, stimuli, call forth the effect, the causal connection is so simple, that there is not even the slightest semblance of freedom. But already in animal life, where that which till then had manifested itself as cause or as stimulus, now appears as a *motive* — and a new world, that of representation, consequently presents itself, and cause and effect lie in different spheres — the causal connection between both, and with it the necessity, are less evident than they were in plants and in inorganic Nature. Nevertheless they are still unmistakable in animals, whose merely intuitive representation stands midway between organic functions induced by stimuli and the deliberate acts of Man. The animal's actions infallibly follow as soon as the perceptible motive is present, unless counter-acted by some

equally perceptible counter-motive or by training; yet here representation is already distinct from the act of volition and comes separately into consciousness. But in Man — whose representation has enhanced itself even to abstract conception and who now derives motives and counter-motives for his actions from a whole invisible thought-world which he carries about with him in his brain and which makes him independent of presence and of perceptible surroundings — this connection no longer exists at all for observation from outside, and even for inward observation it is only knowable through abstract and mature reflection. For these abstract motives, when observed from outside, give an impress of deliberation to all his movements, by which they acquire a semblance of independence that manifestly distinguishes them from those of animals, yet which after all only bears evidence to the fact, that Man is actuated by a class of representations in which animals do not share. Then again, in self-consciousness, the act of volition is known to us in the most immediate way, but the motive in most cases very indirectly, being often even intentionally veiled, out of consideration for our self-knowledge. This process therefore, in coincidence with the consciousness of that true freedom which belongs to the will, as thing in itself outside phenomenon, produces the deceptive illusion that even the single act of volition is unconditioned and free: that is, without a reason; whereas, when the character is given and the motive recognised, every act of volition really follows with the same strict necessity as the changes of which mechanics teach us the laws, and, to use Kant's words, were character and motive exactly known, might be calculated with precisely the same certainty as an eclipse of the moon; or again, to place a very heterogeneous authority by the side of Kant, as Dante says, who is older than Buridan: —

"Intra duo cibi distanti e moventi
D'un modo, prima si morria di fame
Che liber' uomo l'un recasse a' denti."
Paradiso, iv. 1.[95]

PHYSICAL ASTRONOMY.

No part of my doctrine could I have less hoped to see corroborated by empirical science than that, in which the fundamental truth, that Kant's thing in itself (*Ding an sich*) is the Will, is applied by me even to inorganic Nature, and in which I show the active principle in all fundamental forces of Nature to be absolutely identical with what is known to us within ourselves as the Will. — It has therefore been particularly gratifying to me to have found that an eminent empiricist, yielding to the force of truth, had gone so far as to express this paradox in the exposition of his scientific doctrine. I allude to Sir John Herschel and to his "Treatise on Astronomy," the first edition of which appeared in 1833, and a second enlarged one in 1849, under the title "Outlines of Astronomy." Herschel, — who, as an astronomer, was acquainted with gravity, not only in the one-sided and really coarse part which it acts on earth, but also in the nobler one performed by it in universal Space, where the celestial bodies play with each other, betray mutual inclination, exchange as it were amorous glances, yet never allow themselves to come into rude contact, and thus continue dancing their dignified minuet to the music of the spheres, while they keep at a respectful distance from one another — when he comes to the statement of the law of gravitation in the seventh chapter,[96] expresses himself as follows: —

"All bodies with which we are acquainted, when raised into the air and quietly abandoned, descend to the earth's surface in lines perpendicular to it. They are therefore urged thereto by a force or effort, the direct or indirect result of a consciousness and a will existing somewhere, though beyond our power to trace, which force we term *gravity*."[97]

The writer who reviewed Herschel's book in the October number of the "Edinburgh Review" of 1833, anxious, as a true Englishman, before all things to prevent the Mosaic record[98] from being imperilled, takes great umbrage at this passage, rightly observing that it cannot refer to the will of God Almighty, who has called Matter and all its properties into being; he utterly refuses to recognise the validity of the proposition itself, and denies that it follows consistently from the preceding § upon which Herschel wishes to found it. My opinion is, that it undoubtedly would logically follow from that § (because the contents of a conception are determined by

its origin), but that the antecedent itself is false. It asserts namely, that the origin of the conception of causality is experience, more especially such experience as we ourselves make in acting by means of our own efforts upon bodies belonging to the outer world. It is only in countries like England, where the light of Kantian philosophy has not yet begun to dawn, that the conception of causality can be thought of as originating in experience (professors of philosophy who pooh-pooh Kant's doctrines and think me beneath their notice being left out of the question); least of all can it be thought of by those who are acquainted with my proof of the *à priority* of that conception, which differs completely from Kant's proof and rests upon the fact, that knowledge of causality must necessarily precede all perception of the outer world itself as its condition; since perception is only brought about through the *transition* — effected by the understanding — from the sensation in the organ of sense to its *cause*, which cause now presents itself as an *object* in Space, itself likewise an *à priori* intuition. Now, as the perception of objects must be anterior to our conscious action upon them, the experience of that conscious action cannot be the origin of the conception of causality; for, before I can act upon things, they must first have acted upon me as motives. I have entered fully into all that has to do with this in my chief work,[99] and in the second edition of my treatise on the Principle of Sufficient Reason, § 21,[100] where the assumption adopted by Herschel finds special refutation; it is therefore useless to enter into it once more here. But it would be even quite possible to refute this assumption empirically, since it would necessarily follow from it, that a man who came into the world without arms or legs, could never attain any knowledge of causality or perception of the outer world. Now Nature has effectually disproved this by a case, of which I have reproduced the account from its original source in the above-mentioned chapter of my chief work, p. 40.[101] — In this assertion of Herschel's therefore, we have another instance of a right conclusion drawn from wrong premisses. Now this always happens when we have obtained immediate insight into a truth by a right *aperçu* but are at a loss to find out and clearly define our reasons for knowing it, owing to our inability to bring them to clear consciousness. For, in all original insight, conviction exists before proof: the proof being invariably excogitated afterwards.

The immediate manifestation of gravity is more evident in each part of liquid, than of solid, matter, owing to the perfect freedom of motion of the

parts among each other. In order therefore to penetrate into this *aperçu*, which is the true source of Herschel's assertion, let us look attentively at a torrent dashing headlong over rocks and ask ourselves whether so determined an impetus, so boisterous a vehemence, can arise without an exertion of strength, and whether an exertion of strength is conceivable without will. And so it is precisely in every case in which we become aware of anything moving spontaneously, of any primary, uncommunicated force: we are constrained to think its innermost essence as will. — This much at any rate is certain, that Herschel, like all the empiricists in so many different branches of science whose evidence I have quoted above, had arrived here at the limit where nothing more is left behind the Physical but the Metaphysical; that this had brought him to a standstill, and that he, as well as the rest of them, was unable to find anything beyond that limit, but the *will*.

Herschel moreover, like most of these empiricists, is here still hampered by the opinion that will is inseparable from consciousness. As I have expatiated enough above upon this fallacy, and its correction through my doctrine, it is needless for me to enter into it here again.

The attempt has repeatedly been made, since the beginning of this century, to ascribe *vitality* to the inorganic world. Quite wrongly: for living and inorganic are convertible conceptions, and with death the organic ceases to be organic. But no limit in the whole of Nature is so sharply drawn as the line which separates the organic from the inorganic: that is to say, the line between the region in which Form is the essential and permanent, Matter the accidental and changing, — and the region in which this relation is entirely reversed. This is no vacillating boundary like that perhaps between animals and plants, between solid and liquid, between gas and steam: to endeavour to destroy it therefore, is intentionally to bring confusion into our ideas. On the other hand, I am the first who has asserted that a *will* must be attributed to all that is lifeless and inorganic. For, with me, the will is not, as has hitherto been assumed, an accident of cognition and therefore of life: but life itself is manifestation of will. Knowledge, on the contrary, is really an accident of life, and life of Matter. But Matter itself is only the perceptibility of the phenomena of the will. Therefore we are compelled to recognise *volition* in every effort or tendency which proceeds from the nature of a material body, and properly speaking constitutes that nature, or manifests itself as phenomenon by means of that nature; and there

can consequently be no Matter without manifestation of will. The lowest and on that account most universal manifestation of will is *gravity*, wherefore it has been called a primary and essential property of Matter.

The usual view of Nature assumes *two* fundamentally different principles of motion, therefore it supposes that the movement of a body may have *two different origins*: *i.e.*, that it proceeds either from the inside, in which case it is attributed to the *will*; or from the outside, and then it is occasioned by *causes*. This principle is generally taken for granted as a matter of course and only occasionally brought explicitly into prominence; nevertheless, in order to make the case quite certain, I will point out a few passages from the earliest to the latest authors in which it is specially stated. In Phædrus,[102] Plato makes the distinction between that which moves spontaneously from inside (*soul*) and that which receives movement only from outside (*body*) — τὸ ὑφ’ ἑαυτοῦ κινούμενον καὶ τό, ᾧ ἔξωθεν τὸ κινεῖσθαι.[103] — Aristotle establishes the principle in precisely the same way: ἅπαν τὸ φερόμενον ἢ ὑφ’ ἑαυτοῦ κινεῖται, ἢ ὑπ’ ἄλλου (*quidquid fertur a se movetur, aut ab alio*).[104] He returns to the subject in the next Book, chap. 4 and 5, and connects it with some explanatory details which lead him into considerable perplexity, on account precisely of the fallacy of the antithesis.[105] — In more recent times again J. J. Rousseau brings forward the same antithesis with great *naïveté* and candour in his famous “Profession de foi du vicaire Savoyard:”[106] “*J’aperçois dans les corps deux sortes de mouvement, savoir: mouvement communiqué et mouvement spontané ou volontaire: dans le premier la cause motrice est étrangère au corps mû; et dans le second elle est en lui-même.*” — But even in our time and in the stilted, puffed-up style which is peculiar to it, Burdach holds forth as follows:[107] “The cause that determines a movement lies either inside or outside of that which moves. Matter is external existence; it has powers of motion, but it only brings them into play under certain spacial conditions and external oppositions: the soul alone is an ever active and internal thing, and only those bodies which have souls find within themselves inducement to move, and move of their own free will, independently of outer mechanical circumstances.”

Now here however I must say, as Abélard once did: *si omnes patres sic, at ego non sic*: for, in opposition to this principle, however great may be its antiquity and universality, my doctrine maintains, that there are *not* two origins of movement differing fundamentally from one another; that

movement does *not* proceed either from inside, when it is ascribed to the will, or from outside, when it is brought about by causes; but that both things are inseparable and take place simultaneously with every movement made by a body. For movement which is admitted to arise from the *will*, always presupposes a *cause* also: this cause, in beings that have knowledge, is a *motive*; but without it, even in these beings, movement is impossible. On the other hand, the movement of a body which is admitted to have been brought about by an outward *cause*, is nevertheless in itself a manifestation of the *will* of that body which has only been evoked by that cause. Accordingly there is only one, uniform, universal and exceptionless principle of all movement, whose inner condition is *will* and whose outer occasion is *cause*, which latter may also take the form of a *stimulus* or of a *motive*, according to the nature of the thing moved.

All that is known to us of things in a merely empirical or *à posteriori*, way, is in itself *will*; whereas, so far as they can be determined *à priori*, things belong exclusively to *representation*, to mere phenomenon. Natural phenomena therefore become proportionately less easy to comprehend, the more distinctly the will manifests itself in them, *i.e.* the higher they stand on the scale of beings; whereas, they become more and more comprehensible the smaller the amount of their empirical content, because they remain more and more within the sphere of mere representation, the forms of which, known to us *à priori*, are the principle of comprehensibility. Accordingly, it is only so long as we limit ourselves to this sphere — that is to say, only when we have before us mere representation, mere form without empirical content — that our comprehension is complete and thorough: that is, in the *à priori* sciences, Arithmetic, Geometry, Phoronomy and Logic. Here everything is in the highest degree comprehensible; our insight is quite clear and satisfactory: it leaves nothing to be desired, since we are even unable to conceive that anything could be otherwise than it is. This comes from our having here exclusively to do with the forms of our own intellect. Thus the more we are able to comprehend in a relation, the more it consists of mere phenomenon and the less it has to do with the thing in itself. Applied Mathematics, Mechanics, Hydraulics, &c. &c., deal with the lowest degrees of objectification of the will, in which the largest part still remains within the sphere of mere representation; nevertheless even here there is already an

empirical element which stands in the way of entire comprehension, which makes the transparency less complete, and in which the inexplicable shows itself. For the same reason, only few departments of Physics and of Chemistry continue to admit of a mathematical treatment; whereas higher up in the scale of beings this has to be entirely done away with, precisely because of the preponderance of content over form in these phenomena. This content is will, the *à posteriori*, the thing in itself, the free, the causeless. Under the heading "Physiology of Plants," I have shown how — in beings that live and have knowledge — motive and act of will, representation and volition, separate and detach themselves more and more distinctly one from the other, the higher we ascend in the scale of beings. Now, in inorganic Nature also, the cause separates itself from the effect in just the same proportion, and the purely empirical — which is precisely phenomenon of the will — detaches itself more and more prominently; but, just with this, comprehensibility diminishes. This point merits fuller investigation, and I request my readers to give their whole and undivided attention to what I am about to say, as it is calculated to place the leading thought of my doctrine in the strongest possible light, both as to comprehensibility and cogency. But this is all I can do; for it is beyond my power to induce my contemporaries to prefer thoughts to verbiage; I can only console myself for not being the man of the age.

On the lowest step of the scale of Nature, cause and effect are quite homogeneous and quite equivalent. Here therefore we have perfect comprehension of the causal connection: for instance, the cause of the movement of one ball propelled by impact, is the movement of another, which loses just as much movement as the first one receives. Here causality is in the highest degree intelligible. What notwithstanding still remains mysterious, is restricted to the possibility of the passage of movement — of a thing incorporeal — from one body to another. The receptivity of bodies in this mode is so slight, that the effect to be produced has to pass over completely from its cause. The same holds good of all purely mechanical influences; and if they are not all just as instantaneously understood, it is either because they are hidden from us by accessory circumstances, or because we are confused by the complicated connection of many causes and effects. In itself, mechanical causality is everywhere equally, that is, in the highest degree, comprehensible; because cause and effect do not differ here as to *quality*, and because where they differ as to *quantity*, as in the lever,

mere Space and Time relations suffice to make the thing clear. But as soon as weights come also into play, a second mysterious element supervenes, *gravity*: and, where elastic bodies are concerned, *elasticity* also. — Things change as soon as we begin to ascend in the scale of phenomena. Heat, considered as cause, and expansion, liquefaction, volatilization or crystallization, as effects, are not homogeneous; therefore their causal connection is not intelligible. The comprehensibility of causality has diminished: what a lower degree of heat caused to liquefy, a higher degree makes evaporate: that which crystallizes with less heat, melts when the heat is augmented. Warmth softens wax and hardens clay; light whitens wax and blackens chloride of silver. And, to go still further, when two salts are seen to decompose each other mutually and to form two new ones, elective affinity presents itself to us as an impenetrable mystery, and the properties of the two new bodies are not a combination of the properties of their separate elements. Nevertheless we are still able to follow the process and to indicate the elements out of which the new bodies are formed; we can even separate what has been united and restore the original quantities. Thus noticeable heterogeneousness and incommensurability between cause and effect have here made their appearance: causality has become more mysterious. And this becomes still more apparent when we compare the effects of electricity or of the Voltaic pile with their causes, *i.e.* with the friction of glass, or the piling and oxidation of the plates. Here all similarity between cause and effect at once vanishes; causality becomes shrouded in a thick veil, which men like Davy, Faraday and Ampère have strenuously endeavoured to lift. The only thing now discernible through that veil, are the laws ruling its mode of action, which may be brought into a schema such as + E - E, communication, distribution, shock, ignition, analysis, charging, isolation, discharging, electric current, &c. &c., to this schema we are able to reduce and even to direct the effect; but of the process itself we know nothing: that remains an *x*. Here therefore cause and effect are completely heterogeneous, their connection is unintelligible, and we see bodies show great susceptibility to causal influences, the nature of which remains a secret for us. Moreover in proportion as we mount higher in the scale, the effect seems to contain more, the cause less. When we reach organic Nature therefore, in which the phenomenon of life presents itself, this is the case in a far higher degree still. If, as is done in China, we fill a pit with decaying wood, cover it with leaves from the same tree as the

wood, and pour a solution of sulphur repeatedly over it, an abundant crop of edible mushrooms will spring up. A world of rapidly moving *infusoria* will arise from a little hay well watered. What a difference lies here between effect and cause! How much more does the former seem to contain than the latter! When we compare the seed, sometimes centuries, nay even thousands of years old, with the tree, or the soil with the specifically and strikingly different juices of innumerable plants — some healthy, some poisonous, some again nutritious — which spring from the same earth, upon which the same sun shines and the same rain falls, all resemblance ceases, and with it all comprehensibility for us. For here causality already appears in increased potency: that is, as stimulus and as susceptibility for stimulus. The schema of cause and effect alone has remained; we know that this is cause, that effect; but we know nothing whatever of the nature and disposition of causality. Between cause and effect there is not only no qualitative resemblance, but no quantitative relation: the relatively greater importance of the effect as compared with its cause increases more and more; the effect of the stimulus too does not augment in proportion with the enhancement of that stimulus; in fact just the contrary often takes place. Finally, when we come to the sphere of beings which have knowledge, there is no longer any sort of resemblance or relation between the action performed and the object which, as representation, evokes it. Animals, however, as they are restricted to *perceptible* representations, still need the *presence* of the object acting as a motive, which action is then immediate and infallible (if we leave training, *i.e.* habit enforced by fear, out of the question). For animals are unable to carry about with them conceptions that might render them independent of present impressions, enable them to reflect, and qualify them for deliberate action. Man can do this. Therefore when at last we come to rational beings, the motive is even no longer a present, perceptible, actually existing, real thing, but a mere conception having its present existence only in the brain of the person who acts, but which is extracted from many multifarious perceptions, from the experience of former years, or has been handed down in words. Here the separation between cause and effect is so wide, the effect has grown so much stronger as compared with the cause, that the vulgar mind no longer perceives the existence of a cause at all, and the acts of the will appear to it to be unconditioned, causeless: that is to say, free. This is just why, when we reflect upon them from outside, the movements of our own body present

themselves as if they took place without cause, or to speak more properly, by a miracle. Experience and reflection alone teach us that these movements, like all others, are only possible as the effects of causes, here called motives, and that, on this ascending scale, it is only as to material reality that the cause has failed to keep pace with the effect; whereas it has kept pace with it as to dynamical reality, energy. — At this degree of the scale therefore — the highest in Nature — causality has become less intelligible to us than ever. Nothing but the bare schema, taken in a quite general sense, now remains, and the ripest reflection is needed to recognise its applicability and the necessity that schema brings with it everywhere.

In the Grotto of Pausilippo, darkness continues to augment as we advance towards the interior; but when once we have passed the middle, day-light again appears at the other end and shows us the way; so also in this case: just at the point where the outwardly directed light of the understanding with its form of causality, gradually yielding to increasing darkness, had been reduced to a feeble, flickering glimmer, behold! we are met by a totally different light proceeding from quite another quarter, from our own inner self, through the chance circumstance, that we, the judges, happen here to be the very objects that are to be judged. The growing difficulty of the comprehension of the causal nexus, at first so clear, had now become so great for perception and for the understanding — the agent in it — that, in animal actions, the very existence of that nexus seemed almost doubtful and those actions appeared to be a sort of miracle. But, just at this point, the observer receives from his own inner self the direct information that the agent in them is the will — that very will, which he knows better and more intimately than anything that external perception can ever supply. This knowledge alone must be the philosopher's key to an insight into the heart of all those processes in unconscious Nature, concerning which causal explanation — although, here, to be sure, more satisfactory than in the processes last considered, and the clearer, the farther those processes were removed from these — nevertheless had still left an unknown *x*, and could never quite illumine the inside of the process, even in a body propelled by impact or attracted by gravity. This *x* had continued expanding till finally, on the highest degrees of the scale, it had wholly repelled causal explanation. But then, just when the power of causal explanation had been reduced to a minimum, that *x* revealed itself as *the will* — reminding us of Mephistopheles when, yielding to Faust's learned

exorcisms, he steps forth out of the huge grown poodle whose kernel he was. In consequence of the considerations I have here set forth at length, we can surely hardly avoid recognising *the identity of this x*, even on the lowest degrees of the scale, where it was but faintly perceptible; then higher up, where it extended its obscurity more and more; and finally on the highest degrees, where it cast a shadow upon all things — till, at the very top, it reveals itself to our consciousness in our own phenomenal being, as *the will*. The two primarily different sources of our knowledge, that is to say the inward and the outward source, have to be connected together at this point by reflection. It is quite exclusively out of this connection that our comprehension of Nature, and of our own selves arises; but then the inner side of Nature is disclosed to our intellect, which by itself alone can never reach further than to the mere outside; and the mystery which philosophy has so long tried to solve, lies open before us. For then indeed we clearly see what the Real and the Ideal (the thing in itself and the phenomenon) properly are; and this settles the principal question which has engaged the attention of philosophers since Descartes: that is to say, the question as to the relation between these two, whose complete diversity Kant had shown most thoroughly and with unexampled depth, yet whose absolute identity was immediately afterwards proclaimed by humbugs on the credit of intellectual intuition. But if we decline to avail ourselves of this insight, which is really the one strait gate to truth, we can never acquire comprehension of the intrinsic essence of Nature, to which absolutely no other road leads; for then indeed we fall into an irremovable error. Then, as I have already said, we maintain the view, that motion has two radically different primary principles with a solid partition-wall between them: *i.e.* movement by means of causes, and movement by means of the will. The first of these must then remain for ever incomprehensible as to its innermost essence, because, after all its explanations, there is still left that unknown *x* which contains the more, the higher the object under consideration stands in the scale of beings; while the second, movement by the will, presents itself as entirely disconnected from the principle of causality; as without reason; as freedom in individual actions: in other words, as completely opposed to Nature and utterly unexplainable. On the other hand, if the above-mentioned union of our external and internal knowledge has once been accomplished at the point where both meet, we then recognise two identities in spite of all accidental differences. That is to say, we recognise the identity

of causality with itself on every degree of the scale of beings, and the identity of the *x*, which at first was unknown (*i.e.* of physical forces and vital phenomena), with the will which is within us. We recognise, I say, firstly the essential identity of causality under the various forms it is forced to assume on the different degrees of the scale, as it may manifest itself, now as a mechanical, chemical, or physical cause, now as a stimulus, and again as a perceptible or an abstract motive: we know it to be one and the same, not only when a propelling body loses as much movement as it imparts by impact, but also when in the combats of thought against thought, the victorious one, as the more powerful motive, sets Man in motion, a motion which follows with no less necessity than that of the ball which is struck. Where we ourselves are the things set in motion, where therefore the kernel of the process is well and intimately known to us, instead of allowing ourselves to be dazzled and confused by this light and thereby losing sight of the causal connection as it lies before us everywhere else in the whole of Nature; instead of shutting out this insight for ever, we now apply the new knowledge we have acquired from within as a key to the knowledge of things outside us, and then we recognise the second identity, that of our will with the hitherto mysterious *x* that remains over after all causal explanation as an insoluble residue. Consequently we then say: even in cases in which the effect is brought about by the most palpable cause, the mysterious *x* in the process, the real innermost core of it, the true agent, the *in-itself* of all phenomena — which, after all, is only given us as representation and according to the forms and laws of representation — is essentially one and the same with what is known to us immediately and intimately as *the will* in the actions of our own body, which body is likewise given us as intuition and representation. — This is (say what you will) the basis of true philosophy, and if the present age does not see this, many following ages will. *Tempo è galant' uomo!* (*se nessun altro*). — Thus, just as, on the one hand, the essence of causality, which appears most clearly only on the lowest degree of the objectification of the will, is recognised by us again at every ascending step, even at the highest; so also, on the other hand, is the essence of the will recognised by us at every descending step in that ladder, even at the lowest, although this knowledge is only immediately acquired at the very highest. The old error asserts, that where there is will, there is no causality; and that where there is causality, there is no will. But we say: everywhere where there is causality, there is will; and no will acts

without causality. The *punctum controversiæ* therefore, is, whether will and causality can and must subsist together in one and the same process at the same time. What makes the knowledge, that this is indeed the case, so difficult, is the circumstance, that we know causality and will in two fundamentally different ways: causality entirely from outside, quite indirectly, quite through the understanding; will entirely from inside, quite directly; and that accordingly the clearer the knowledge of the one in each given instance, the less clear is the knowledge of the other. Therefore we recognise the essence of the will least readily, where causality is most intelligible; and, where the will is most unmistakably evident, causality becomes so obscured, that the vulgar mind could venture to deny its existence altogether. — Now, as Kant has taught us, causality is nothing but the form of the understanding itself, knowable *à priori*: that is, the essence of *representation*, as such, which is one side of the world; the other side is *will*: which is the thing in itself. That relative increase and decrease of clearness in inverse proportion of causality and of the will, that mutual advancing and receding of both, depends consequently upon the fact, that the more a thing is given us as mere phenomenon, *i.e.* as representation, the more clearly does the *à priori* form of representation, *i.e.* causality, manifest itself: this is the case in inanimate Nature; conversely, the more immediate our knowledge of the will, the more does the form of representation recede into the background: this is the case with ourselves. That is: the nearer one side of the world approaches to us, the more do we lose sight of the other.

LINGUISTIC.

All that I have to record under this head is an observation of my own, made within the last few years, which seems hitherto to have escaped notice. Yet, that it is worthy of consideration, is attested by Seneca's utterance:[108] *Mira in quibusdam rebus verborum proprietas est, et consuetudo sermonis antiqui quædam efficacissimis notis signat.* Lichtenberg too says: "If one thinks much oneself, one finds a good deal of wisdom deposited in language. It is hardly likely that we have laid it all there ourselves, but rather that a great deal of wisdom really lies there."

In many, perhaps in all, languages, the action even of those bodies which are without intellect, nay of inanimate bodies, is expressed by the words *to will*, so that the existence of a will in these bodies is thus taken for granted; but they are never credited with a faculty for knowing, representing, perceiving or thinking: I know of no expression which conveys this.

Seneca, when speaking of lightning shot down from heaven, says:[109] "*In his, ignibus accidit, quod arboribus: quarum cacumina, si tenera sunt, ita deorsum trahi possunt, ut etiam terram attingant; sed quum permiseris, in locum suum exsilient. Itaque non est quod eum spectes cujusque rei habitum, qui illi non* ex voluntate *est. Si ignem permittis ire quo velit, cœlum repetet.*" In a more general sense Pliny says: *nec quærenda in ulla parte naturæ ratio, sed voluntas*.[110] Nor do we find Greek less fertile in instances. Aristotle, when explaining gravity, says: μικρὸν μὲν μόριον τῆς γῆς, ἐὰν μετεωρισθὲν ἀφεθῇ, φέρεται, καὶ μένειν οὐκ ἐθέλει (*parva quædam terræ pars, si elevata dimittitur, neque vult manere*).[111] And: Δεῖ δὲ ἕκαστον λέγειν τοιοῦτον εἶναι, ὃ φύσει *βούλεται* εἶναι, καὶ ὃ ὑπάρχει, ἀλλὰ μὴ ὃ βίᾳ καὶ παρὰ φύσιν (*unumquodque autem tale dicere oportet, quale naturâ suâ esse vult, et quod est; sed non id quod violentiâ et præter naturam est*).[112] Of great and more than merely linguistic importance is what Aristotle says in his "Ethica magna,"[113] where not only animals, but inanimate beings (fire striving upwards and earth downwards) are explicitly in question, and he asserts that they may be obliged to do something contrary to their nature or their will: παρὰ φύσιν τι, ἢ παρ' ἃ *βούλονται* ποιεῖν, — and therefore rightly places παρ' ἃ βούλονται as a paraphrase of παρὰ φύσιν. — Anacreon, in his 29th Ode, εἱς Βάθυλλον, in ordering the

portrait of his lady-love, says of her hair: Ἕλικας δ᾽ ἐλευθέρους μοι πλοκάμων, ἄτακτα συνθείς, ἄφες, ὡς *θέλωσι*, κεῖσθαι (*capillorum cirros incomposite jungens, sine utut volunt jacere*).[114] In German, Bürger says: "*hinab* will *der Bach, nicht hinan*" (the brook *will* go downwards not upwards). In daily life we constantly hear: "the water boils, it *will* run over,"— "the glass *will* break,"— "the ladder *will* not stand;"— "*le feu ne* veut *pas brûler*."— "*la corde, une fois tordue*, veut *toujours se retordre*." — In English, the verb '*to will*' is even the auxiliary of the future of all the other verbs, thus expressing the notion, that there lies a will at the bottom of every action. In English moreover, the endeavours of all inanimate and unconscious things, are expressly designated by the word *want*, which denotes every sort of human desire or endeavour: "the water *wants* to get out,"— "the steam *wants* to find an issue." — In Italian too we have "vuol *piovere*;" "*quest' orologio non* vuol *andare*." — The conception of willing is besides so deeply rooted in this last language, that it seems to indicate everything that is requisite or necessary: "*ci* vuol *un contrappeso*;" "*ci* vuol *pazienza*."

A very striking instance of this is to be found even in Chinese — a language which differs fundamentally from all those belonging to the Sanskrit family — it is in the commentary to the Y-King,[115] accurately rendered by Peter Regis as follows: "*Yang, seu materia cœlestis*, vult *rursus ingredi, vel* (*ut verbis doctoris Tsching-tse utar*) vult *rursus esse in superiore loco; scilicet illius naturæ ratio ita fert, seu innata lex*."

The following passage from Liebig[116] has decidedly much more than a linguistic signification, for it expresses an intimate feeling and comprehension of the way in which a chemical process takes place. "Aldehyd arises, which with the same *avidity* as sulphurous acid, combines directly with oxygen to form acetic acid." — And again:[117] "Aldehyd, which absorbs oxygen from the air with *great avidity*." As Liebig uses this expression twice in speaking of the same phenomenon, it can hardly be by chance, but rather because it was the only adequate expression for the thing.[118] That most immediate stamp of our thoughts, language, shows us therefore, that every inward impulse must necessarily be conceived as volition; but it by no means ascribes knowledge to things as well. The agreement on this point between all languages, perhaps without a single exception, proves that here we have to do with no mere figure of speech,

but that the verbal expression is determined by a deeply-rooted feeling of the inner nature of things.

ANIMAL MAGNETISM AND MAGIC.

In 1818, when my chief work first appeared, Animal Magnetism had only begun to struggle into existence. But, as to its explanation — although, to be sure, some light had been thrown upon the passive side of it, that is, upon what goes on within the patient, by the contrast between the cerebral and the ganglionic systems, to which Reil had drawn attention, having been taken for the principle of explanation — the active side, the agent proper by means of which the magnetiser evokes all these phenomena, was still completely shrouded in darkness. People groped about among all sorts of material principles of explanation, such as Mesmer's all-permeating ether, or the exhalations from the magnetiser's skin, assumed by Stieglitz to be the cause, &c. &c. At the utmost a nerve-spirit had been recognised and, after all, this was but a word for an unknown thing. The truth had scarcely begun to dawn upon a few persons, whom practice had more deeply initiated. But I was still far from hoping for any direct corroboration of my doctrine from Magnetism.

Dies diem docet however, and the great teacher, experience, has since brought to light an important fact concerning this deep-reaching agent which, proceeding from the magnetiser, produces effects apparently so contrary to the regular course of Nature that the long lasting doubt as to their existence, the stiff-necked incredulity, the condemnation of a Committee of which Lavoisier and Franklin were members, in short, the whole opposition that Magnetism encountered both in its first and second period (with the sole exception of the coarse, unintelligent condemnation without inquiry, which till very lately, prevailed in England) is quite excusable. The fact I allude to is, that this agent is nothing but the *will* of the magnetiser. To-day not a doubt exists on this point, I believe, among those who combine practice with insight; therefore I think it superfluous to quote the numerous assertions of magnetisers in corroboration of it.[119] Time has thus not only verified Puységur's watchword and that of the older French magnetisers: "*Veuillez et croyez!*" *i.e.* "Will with belief!" but this very watchword has even developed into a correct insight of the process itself.[120] From Kieser's "Tellurismus," still probably the most thorough and detailed text book of Animal Magnetism we have, it clearly results, that no act of Magnetism can take effect without the will; on the other hand the

bare will, without any outward action, is able to produce every magnetic effect. Manipulation seems to be only a means of fixing, and so to say incorporating, the will and its direction. In this sense Kieser says: "Inasmuch as the human hand — being the organ by which Man's outward activity is most visibly expressed — is the efficient organ in magnetising, manipulation arises." De Lausanne, a French magnetiser, pronounces himself with still greater precision on this point in the Fourth Book of his "Annales du Magnétisme Animal" (1814-1816), where he says: "*L'action du magnétisme dépend de la seule volonté, il est vrai; mais l'homme ayant une forme* extérieure et sensible, *tout ce qui est à son usage, tout ce qui doit agir sur lui, doit nécéssairement en avoir une, et pour que la volonté agisse, il faut qu'elle employe un mode d'action.*" As, according to my doctrine, the organism is but the mere phenomenon, the visibility, the objectivity of the will; nay, as it is properly speaking only the will itself, viewed as representation in the brain: so also does the outward act of manipulation coincide with the inward act of the will. But where magnetic effects are produced without manipulation, they take place as it were artificially, in a roundabout way, the imagination taking the place of the outer act and even occasionally that of personal presence: wherefore it is much more difficult and succeeds less frequently. Kieser accordingly alleges that the word "Sleep!" or "You must!" said aloud, has a more powerful effect upon a somnambulist than the mere inward willing of the magnetiser. — On the other hand manipulation, and in general outward action, is really an infallible means of fixing the magnetiser's will and promoting its activity; precisely because outward acts are quite impossible apart from all will, the body and its organs being nothing but the visibility of the will itself. This explains the fact, that magnetisers at times magnetise without any conscious effort of volition and almost without thinking, and yet produce the desired effect. On the whole, it is not the consciousness of volition, reflection upon it, that acts magnetically, but pure volition itself, as detached as possible from all representation. In Kieser's directions to magnetisers therefore,[121] we find all thinking and reflecting upon their respective doing and suffering, all conversation between them, forbidden both to physician and patient; also all outward impressions which arouse representations, the presence of strangers, and even daylight. He advises that everything should proceed as unconsciously as possible, as is likewise recommended in charm-cures. The true reason of all this is, that here the

will operates in its primariness, as thing in itself; and this demands the exclusion, as far as possible, of representation, as a different sphere, as secondary to the will. Facts to prove that the real agent in magnetising is the will and each outward act only its vehicle, may be found in all the more recent and more trustworthy writings upon Magnetism, and it would be needless prolixity to repeat them here. Nevertheless I will quote *one* case, not as being especially striking, but as furnished by a remarkable person and having a peculiar interest as his testimony. Jean Paul says in a letter:[122] "Twice in a large company I have made Frau von K. nearly go to sleep by merely looking at her with a *firm will*, no one else knowing anything about it, and before that, I had brought on palpitation of the heart and pallor to such a degree that Dr. S. had to be summoned to her assistance."[123] Nowadays too, merely laying and keeping hold of the patient's hands while fixing the eye steadily upon him, is frequently substituted with complete success for the customary manipulation; precisely because even this outward act is suited to fix the will in a determined direction. But this immediate power which the will can exercise over other persons, is brought to light best of all by the admirable experiments made, even in public, by M. Dupotet and his pupils in Paris, in which a stranger is guided and determined at pleasure by the magnetiser's mere will, aided by a few gestures, and is even forced into the most extraordinary contortions. An apparently quite honestly written pamphlet, entitled "First glance into the wonder-world of Magnetism," by Karl Scholl (1853), contains a brief account of this.

In the "Communications concerning the somnambulist, Auguste K. in Dresden" (1843), we find the truth in question confirmed in another way by what the somnambulist herself says, p. 53: "I was half asleep and my brother wished to play a piece he knew. As I did not like it, I requested him not to play it; nevertheless he tried to do so and then, by means of my firm will that he should not, I succeeded in making him unable to remember the piece, in spite of all his endeavours." — The thing is however brought to a climax when this immediate power of the will is extended even to inanimate bodies. However incredible this may appear, we have nevertheless two accounts of it coming from entirely different quarters. In the book just mentioned,[124] it is related and testified by witnesses, that Auguste K. caused the needle of the compass to deviate at one time 7° and at another 4°, this experiment moreover being repeated four times. She did this moreover

without any use of her hands, through her mere will, by looking steadily at it. — The Parisian somnambulist, Prudence Bernard, again in a public *séance* in London, at which Mr. Brewster, the physicist's son and two other gentlemen from among the spectators acted as jurors, made the compass needle deviate and follow her movements by simply turning her head round.[125]

Now, if we thus see the will — stated by me to be the thing in itself, the only real thing in all existence, the kernel of Nature — accomplish through the human individual, in Animal Magnetism and even beyond it, things which cannot be explained according to the causal nexus, *i.e.* in the regular course of Nature; if we find it in a sense even annulling Nature's laws and actually performing *actio in distans*, consequently manifesting a supernatural, that is, metaphysical, mastery over Nature — what corroboration better founded on fact could I desire for my doctrine? Was not even Count Szapary, a magnetiser who certainly did not know my philosophy, led by the results of his own experience, after writing the title of his book: "A word about Animal Magnetism, soul-bodies and vital essence,"[126] to add the following remarkable explanatory words: "or physical proofs that the current of Animal Magnetism is the element, and *the will the principle of all spiritual and corporeal life*?"[127] — According to this, Animal Magnetism presents itself directly as *practical Metaphysic*, which was the term used by Bacon of Verulam[128] to define Magic in his classification of the sciences: it is empirical or experimental Metaphysic. — Further, because the will manifests itself in Animal Magnetism downright as the thing in itself, we see the *principium individuationis* (Space and Time), which belongs to mere phenomenon, at once annulled: its limits which separate individuals from one another, are destroyed; Space no longer separates magnetiser and somnambulist; community of thoughts and of motions of the will appears; the state of *clairvoyance* overleaps the relations belonging to mere phenomenon and conditioned by Time and Space, such as proximity and distance, the present and the future.

In consequence of these facts, notwithstanding many reasons and prejudices to the contrary, the opinion has gradually gained ground, nay almost raised itself to certainty, that Animal Magnetism and its phenomena are identical with part of the Magic of former times, of that ill-famed occult art, of whose reality not only the Christian ages by which it was so cruelly persecuted, but all, not excepting even savage, nations on the whole of the

earth, have been equally convinced throughout all ages. The Twelve Tables of the Romans,[129] the Books of Moses, and even Plato's Eleventh Book on Laws, already made its practice punishable by death, and Apuleius' beautiful speech[130] before the court of justice, when defending himself against the charge of practising magic by which his life was menaced, proves how seriously this matter was taken even in the most enlightened Roman period, under the Antonines; since he merely tries to clear himself personally from the charge in question, but by no means contests the possibility of witchcraft and even enters into a host of absurd details such as are wont to figure in all the mediæval trials for witchcraft. The eighteenth century makes an exception as regards this belief in Magic, and this is mainly because Balthasar Becker, Thomasius and some others, with the good intention of putting an end once for all to the cruel trials for witchcraft, declared all magic to be impossible. Favoured by the philosophy of the age, this opinion soon gained the upper hand, although only among the learned and educated classes. The common people have never ceased to believe in witchcraft, even in England; though here the educated classes contrive to unite a degrading religious bigotry with the firm incredulity of a Saint Thomas (or of a Thomasius) as to all facts transcending the laws of impact and counter-impact, acids and alkalis, and refuse to lend an ear to their great countryman, when he tells them that 'there are more things in heaven and earth than are dreamt of in their philosophy.' One branch of Magic is still notoriously preserved and practised among the lower orders, being tolerated on account of its beneficent purpose. This is *curing by charms* (*sympathetische Kuren*, as they are called in German), the reality of which can hardly be doubted. Charming away warts, is one of the commonest forms of this practice, and of this Bacon of Verulam, cautious and empirical though he was, attests the efficacy from personal experience.[131] The charming away of erisypelas in the face by a spell, is another instance, and so often succeeds, that it is easy to convince oneself of its existence. Fever too is often successfully combated by spells, &c. &c.[132] — That, in all this, the real agents are not the meaningless words and ceremonies, but that it is the will of the operator which acts, as in Animal Magnetism, needs no further explanation after what has been said above. For such as are still unacquainted with charm-cures, instances may be found in Kieser.[133] — These two facts therefore, Animal Magnetism and Charm-curing, bear empirical evidence to the possibility of magical, as opposed to

physical, influence, which possibility had been so peremptorily rejected by the past century; since it refused to recognise as possible any other than physical influences brought about in the way of the intelligible nexus of causality.

It is a fortunate circumstance, that the rectification of this view in our time should have come from medical science; because it ensures us at the same time against the danger of the pendulum of opinion receiving too strong an impulse in the contrary direction, and thus carrying us back to the superstition of ruder ages. Besides, as I have said, Animal Magnetism and Charm-curing only save the reality of a part of Magic, which included a good deal more, a considerable portion of which must, for the present at least, remain under the old sentence of condemnation or be left in uncertainty; whereas another portion will at any rate have to be conceived as possible, through its analogy to Animal Magnetism. For Animal Magnetism and Charm-cures are but salutary influences exercised for curative purposes, like those recorded in the "History of Magic" as practised by the so-called (Spanish) *Saludadores*,[134] who nevertheless were also condemned by the Church; whereas Magic was far oftener practised with an evil intent. Nevertheless, to judge by analogy, it is more than probable, that the same inherent force which, by acting directly upon another individuality, can exercise a salutary influence, will be at least as powerful to exercise a prejudicial and pernicious one. If therefore there was reality in any part of ancient Magic beyond what may be referred to Animal Magnetism and curing by charms, it must assuredly have been in that which is called *maleficium* and *fascinatio*, the very thing that gave rise to most of the trials for witchcraft. In Most's book, too, already mentioned,[135] a few facts are related which must undoubtedly be ascribed to *maleficium*; in Kieser,[136] also we find instances of diseases which had been transmitted, especially to dogs, who died of them. In Plutarch[137] we find that *fascinatio* was already known to Democritus, who tried to explain it as a fact. Now admitting these stories to be true, they give us the key to the crime of witchcraft, the zealous persecution of which would therefore not have been quite without reason. For even if in most cases it may have been founded upon error and abuse, we are still not authorized to look upon our forefathers as having been so utterly benighted, as to persecute with the utmost vigour and cruelty for so many ages an absolutely impossible crime. From this point of view moreover, we can also understand that the common

people should still even to the present day persist in attributing certain cases of illness to a *maleficium*, and are not to be dissuaded from this conviction. Now if we are thus induced by the progress of the age to modify the extreme view adopted by the last century concerning the absolute nullity of this ill-famed art — at any rate with respect to some part of it — still nowhere is caution more necessary than here, in order to fish out from the chaos of fraud, falsehood and absurdity contained in the writings of Agrippa von Nettesheim, Wierus, Bodinus, Delrio, Bindsfeldt, &c. &c., the few isolated truths that may lie in them. For, frequent though they may be throughout the world, nowhere have lies and deceit freer play than where Nature's laws are avowedly set aside, nay declared invalid. Here therefore we find the wildest fictions, the strangest freaks of the imagination worked up into an edifice, lofty as the skies, on the narrow foundation of the slight particle of truth there may have been in Magic, and in consequence of this, the most sanguinary atrocities perpetrated age after age. In contemplating such things, the psychological reflection on the unlimited capability of the human intellect for accepting the most incredible absurdities and the readiness of the human heart to set its seal to them by cruelty, prevails over every other.

Yet the modification which has taken place of late in the views of German *savants* respecting magic, is not due exclusively to Animal Magnetism. The deep foundations of it had already been laid by the change in philosophy wrought by Kant, which makes German culture differ fundamentally from that of the rest of Europe, with respect to philosophy as well as to other branches of knowledge. — For a man to be able to smile beforehand at all occult sympathies, let alone magical influences, he must find the world very, nay completely, intelligible. But this is only possible if he looks at it with the utterly superficial glance which puts away from it all suspicion that we human beings are immersed in a sea of riddles and mysteries and have no exhaustive knowledge or understanding either of things or of ourselves in any direct way. Nearly all great men have been of the opposite frame of mind and therefore, whatever age or nation they belonged to, have always betrayed a slight tinge of superstition. If our natural mode of knowing were one that handed over to us things in themselves immediately and consequently gave us the absolutely true relations and connections of things, we might then, no doubt, be justified in rejecting *à priori*, therefore unconditionally, all prescience of future events,

all apparitions of absent, of dying, let alone of deceased persons, and all magical influence. But if all that we know is, as Kant teaches, mere phenomenon, the forms and laws of which do not extend to things in themselves, it must be obviously premature to reject all foreknowledge, all apparitions and all magic; since that rejection is based upon laws, whose *à priori* character precisely restricts them to phenomena; whereas things in themselves, to which even our own inner self must belong, remain untouched by them. But it is quite possible for these very things in themselves to have relations with us from which the above-mentioned occurrences may have arisen, concerning which accordingly we have to wait for the decision *à posteriori*, and must not forestall it. That the English and French should persist in denying *à priori* all such occurrences, comes at the bottom from the influence of Locke's philosophy, under which these nations still stand as to all essential points, and by which we are taught that, after merely subtracting sensation, we know things in themselves. According to this view therefore, the laws of the material world are held to be ultimate, and no other influence than *influxus physicus* is admitted. Consequently these nations believe, it is true, in a physical, but not in a metaphysical, science, and therefore reject all other than so-called "Natural Magic:" a term which contains the same *contradictio in adjecto* as "Supernatural Physics," but is nevertheless constantly used quite seriously, while the latter was used but once, and then in joke, by Lichtenberg. On the other hand, the common people, with their universal readiness to give credit to supernatural influences, express by it in their own way the conviction, that all things which we perceive and comprehend are mere phenomena, not things in themselves; although, with them, conviction is only felt. I quote the following passage from Kant's "Grundlegung zur Metaphysik der Sitten," as a proof that this is not saying too much: "There is an observation requiring no great subtlety of reflection, which we may on the contrary suppose the most ordinary understanding capable of making, albeit in its own way and by an obscure distinction of the faculty of judgment, which it calls feeling. It is this: that all our involuntary representations (such as those of the senses) give us no further knowledge of objects than as they affect us, whereby we are left in ignorance as to what those objects may be in themselves; that, as far as this sort of representation is concerned therefore, we are still only able by this means to attain knowledge of phenomena, but never of *things in themselves*, even by dint of the utmost

clearness and the most strenuous attention the understanding is able to give to this point. When once this distinction is made, however, it stands to reason, that the existence of something else behind these phenomena, something which is not phenomenon, *i.e.* the thing in itself, has still to be admitted and assumed."[138]

When we read D. Tiedemann's "History of Magic,"[139] we are astonished at the persistency with which mankind have clung to the thought of Magic in all places and at all times, notwithstanding frequent failure; and we come to the conclusion, that this thought must, to say the least, be deeply rooted in human nature, if not in things in general, and cannot be a mere arbitrary creation of the fancy. Although Magic is differently defined by the various authors who have treated of it, the fundamental thought which predominates in all its definitions is nevertheless unmistakeable. For the opinion, that there must be another quite different way of producing changes in the world besides the regular one through the causal nexus between bodies, and one moreover which is not founded at all upon that nexus, has found favour in all ages and countries. Therefore also the means belonging to this second way appeared absurd, when they were viewed in the same light as the first; since the cause applied was obviously not suited to the effect intended and a causal nexus between them was impossible. But here it was assumed, that apart from the outer connection between the phenomena of this world on which the *nexus physicus* is founded, there must exist another besides, passing through the very essence in itself of all things: a subterranean connection as it were, by means of which immediate action was possible from *one* point of the phenomenon on to every other point, through a *nexus metaphysicus*;

that accordingly, it must be possible to act upon things from inside, instead of from outside, as is usual;

that it must be possible for phenomenon to act upon phenomenon by means of that being in itself, which is one and the same in all phenomena;

that, just as we act causally as *natura naturata*, we might probably be able to act also as *natura naturans*, and momentarily to enable the microcosm to play the part of the macrocosm;

that, however firm the partition walls of individuation and separation might be, they might nevertheless occasionally permit a communication to take place as it were behind the scenes, or like a secret game under the table; and

that, just as a neutralisation of individual isolation takes place in somnambulistic *clairvoyance*, so likewise might a neutralisation of the will in the individual be possible. Such a thought as this cannot have arisen empirically, nor can it have been confirmation through experience that has preserved it throughout all ages and in all countries: for in the majority of cases experience must result downright unfavourably to it. I opine therefore, that the origin of this thought, which has universally held its ground with the whole of mankind and, in spite of so much conflicting experience, in defiance of common sense, has never been eradicated, must be sought at great depth: namely in the inward feeling of the omnipotence of the will in itself — of that will, which constitutes at once the inner essence of Man and of the whole of Nature — and in the assumption connected with it that, somehow or other, this omnipotence might possibly for once make itself felt, even when proceeding from the individual. People were unable to investigate and distinguish the difference between the capabilities of the will as thing in itself and the same will in its individual manifestation; but they assumed without further ado, that under certain circumstances, the will might be enabled to break through the barriers of individuation. For the above-mentioned feeling rebelled obstinately against the knowledge forced upon it by experience, that

"Der Gott der mir im Busen wohnt,
Kann tief mein Innerstes erregen,
Der über allen meinen Kräften thront,
Er kann nach Aussen nichts bewegen."

According to the fundamental thought just expounded, we find that the physical medium used in all attempts at magic, never was regarded in any other light than in that of a vehicle for a thing metaphysical; otherwise it could evidently stand in no relation whatever to the effect contemplated. These media consisted in cabalistic words, symbolical actions, traced figures, wax images, &c. &c. We see too that, according to the original feeling, what this vehicle conveyed, was in the last resort always an act of *volition* that had been connected with it. The very natural inducement to do this, was the observation, that every moment men became aware of a completely unaccountable, that is, evidently metaphysical, agency of the will, in the movements of their own bodies. Might not this agency, they thought, be extended to other bodies also? To find out a way to annul the isolation in which the will finds itself in each individual, and to extend the

immediate sphere of the will's action beyond the organism of the person willing, was the aim of Magic.

A great deal was nevertheless still wanting ere this fundamental thought, from which Magic seems properly to have sprung, could pass over at once into distinct consciousness and be recognised *in abstracto*, and ere Magic could at once understand itself. Only a few thoughtful and learned writers of former ages — as I mean soon to prove by quotations — express the distinct thought, that it is in *the will* itself that the magic power lies, and that the strange signs and acts together with the senseless words that accompanied them, which passed for the means of exorcising and the connecting link with demons, are in fact merely vehicles and means for fixing *the will*, by which the act of volition, which is to act magically, ceases to be mere wish and becomes deed, or, to use the language of Paracelsus, "receives a *corpus*," and the individual will in a sense distinctly proclaims that it is now acting as general will, as will in itself. For in every act of Magic — charm-cure or whatever else it may be — the outward action (the connecting link) is exactly what the passes are in magnetising: *i.e.* not what is really essential, but the mere vehicle, that by which the will, the only real agent, is directed and fixed in the material world and enters into reality. As a rule therefore, it is indispensable. — From the rest of the writers of those times we gather that, in conformity with that fundamental thought of Magic, their only aim was to obtain absolute, arbitrary power over Nature. But they were unable to elevate themselves to the thought that this power must be a *direct* one; they conceived it, on the contrary, absolutely as an *indirect* one. For all religions in all countries had placed Nature under the dominion of gods and of demons. Now, it was the magician's endeavour to subject these gods and demons to his will, to induce, nay, to force them to serve him; and he attributed all that he succeeded in achieving to their agency, just as Mesmer attributed the success of his Magnetism to the magnetic rods he held in his hands, instead of to his will which was the real agent. It was in this sense that all polytheistic nations took the matter, and even Plotinus,[140] but more especially Iamblichus, understood Magic: that is, as *Theurgy*, an expression which Porphyry was the first to use. That divine aristocracy, Pantheism, was favourable to this interpretation, since it distributed the dominion over the different forces of Nature among as many gods and demons — mostly mere personifications of natural forces — and the magician, by persuasion or by

force, subjected now one, now the other of these divinities to his power and made them do his bidding. But in a Divine Monarchy, where all Nature obeys a single ruler, the thought of contracting a private alliance with the Almighty, let alone of exercising sovereignty over him, would have been too audacious. Therefore where Judaism, Christianity or Islam prevailed, the omnipotence of the one God stood in the way of this interpretation of Magic: an omnipotence which the magician could not venture to attack. He had no alternative therefore, but to take refuge with the Devil, and with this rebellious spirit — perhaps even direct descendant of Ahriman — to whom some power over Nature was still attributed, he now entered into a compact, by which he ensured to himself his assistance. This was "necromancy" (the 'black art'). Its antithesis, 'white Magic,' was opposed to it by the circumstance that, in it, the magician did not make friends with the Devil, but rather solicited the permission, not to say co-operation, of the Almighty himself, to intercede with the angels; oftener still, he invoked devils by pronouncing the rarer Hebrew names and titles of the One God, such as Adon-Ai, &c. &c., and compelled them to obey him, without promising them anything in return for their services, in a hell-compulsion[141] (*Höllenzwang*). — But all these mere interpretations and outward trappings of the thing were received so entirely as its essence and as objective processes, that writers like Bodinus, Delrio, Bindsfeldt, &c., whose knowledge of magic was second-hand and not derived from personal experience, all assert the essential characteristic of Magic to be, that it does not act either through forces of Nature or in a natural way, but through the assistance of the Devil. This view was, and long remained, current everywhere, locally modified according to the religions which prevailed in different countries. The laws against sorcery and the trials for witchcraft were based upon it; likewise, wherever the possibility of Magic was contested, the attacks were generally directed against this opinion. An objective view, such as this, was an inevitable consequence of the decided Realism which prevailed throughout ancient and mediæval Europe and which Descartes was the first to disturb. Till then, Man had not learnt to direct the light of speculative thought towards the mysterious depths of his own inner self, but, on the contrary, had sought everything outside himself. Above all the thought of making the will he found within him rule over Nature, was so bold, that people would have been alarmed by it: therefore it was made to rule over fictitious beings, supposed by the prevailing

superstition to have command over Nature, in order through them to obtain at least indirect mastery over Nature. Every sort of god or demon moreover, is always a hypostasis, by which believers of all sects and colours bring to their own comprehension the *Metaphysical*, that which lies *behind* Nature, that which gives her existence and consistence and consequently rules over her. Thus, when it is said, that Magic acts by the help of demons, the meaning which lies at the bottom of this thought still is, that it is an agency which is not physically, but *metaphysically* exercised: that it is not a natural, but a supernatural, agency. Now if, in the small amount of fact which speaks in favour of the reality of Magic: that is, in Animal Magnetism and charm-cures, we still do not recognise anything but an immediate action of the will which here manifests its direct power outside, instead of inside, the individual; if moreover, as I am about to show and to substantiate by decisive, unequivocal citations, those who are more deeply initiated into ancient Magic, derive all its effects from the magician's will alone: this is surely strong empirical evidence in support of my doctrine, that the Metaphysical in general, that which alone exists apart from representation, the *thing in itself* of the universe — is nothing but what is known to us within ourselves as *the will*.

Now, if the direct power which may occasionally be exercised over Nature by the will, was conceived by those magicians as a merely indirect one, acquired by the help of demons, this still could not prevent its efficiency wherever and whenever it may have taken place. For, precisely because, in things of this kind, the will acts in itself, in its primariness, therefore apart from representation, its efficiency cannot be frustrated by erroneous conceptions of the intellect; on the contrary, the distance here is a wide one between theory and practice: the errors of the former do not stand in the way of the latter, nor does a correct theory qualify for practice. Mesmer, in the beginning, attributed his agency to the magnetic rods he held in his hands and later on explained the wonders of Animal Magnetism by a materialistic theory of a subtle, all-permeating fluid; nevertheless he produced wonderfully powerful effects. I once myself knew the proprietor of an estate, whose peasants were wont by tradition to have their feverish attacks dispelled by a spell of their master's. Now, although he believed he had convinced himself of the impossibility of all such things, yet he continued good-naturedly to comply with their wish as usual, and indeed often succeeded in relieving them. This success he ascribed to his peasants'

firm belief, forgetting that a similar faith ought also to bring success to the medical treatment which is so often applied with complete inefficacy to believing patients.

Now, if Theurgy and Demonomagic, as described above, were but the mere interpretation and outward trappings of the thing, the mere husk, at which the majority were content to stop short: there were nevertheless some, who went below the surface and quite recognised that the agent in influences supposed to proceed from magic, was absolutely nothing but *the will*. We must not however look for such deeper observers as these among the discountenancers and antagonists of Magic, and the majority of the writers on this subject belong precisely to these: they derived their knowledge exclusively from Courts of Justice and from the examination of witnesses, so that they merely describe the outside of the matter; and, if at any time they chanced, through confessions, to gain an insight into the inner processes they took good care not to betray that knowledge, lest, by doing so, they should contribute to diffuse the terrible vice of sorcery. To this class belong Bodinus, Delrio, Bindsfeldt, and others. For information as to the real nature of the thing, we must on the contrary go to philosophers and investigators of Nature, who wrote in those times of prevailing superstition. Now, from what they say, it clearly follows, that the real agent in Magic, just as in Animal Magnetism, is nothing but *the will*. Here I must quote some passages in support of this assertion.[142] Theophrastus Paracelsus especially disclosed perhaps more concerning the inner nature of Magic than any other writer, and does not even hesitate to give a minute description of the processes used in it.[143] — He says:[144] "To be observed concerning wax images: if I bear malice in my will against anyone, that malice must be carried out by some medium or *corpus*. Thus it is possible for my spirit to stab or wound another person without help from my body in using a sword, merely by my *fervent desire*. Therefore it is also possible for me to convey my opponent's spirit into the image by my *will* and then to deform or paralyze it at pleasure. — You must know, that the influence of the *will* is a great point in medicine. For if a man hate another and begrudge him anything good, it is possible that if he curse him, that curse may take effect. — This occurs also with animals and more easily than with men; for the spirit of man has far greater power of resistance than that of animals."

And p. 375: "It follows from this, that one image has magic power over another, not by virtue of the characters or anything of that kind impressed

on the virgin wax; but the imagination overcomes its own constellation, so as to become a means for fulfilling the will of its heaven, *i.e.* of its man."

p. 334: "All the imagining of man comes from his heart. The heart is the sun of the microcosm. And all the imagining of man passes from the small sun of the microcosm into the sun of the great Universe, into the heart of the macrocosm. Thus the *imaginatio* of the microcosm is a seed which becomes material," &c.

p. 364: "It suffices for you to know what rigorous imagination does, which is the beginning of all magical works."

p. 789: "Even my thought therefore is a looking at a mark. Now I must not turn my eye with my hands in this or that direction; but my imagination turns it as I wish. And this is also to be understood of walking: I desire, I propose to myself, therefore my body moves, and the firmer my thoughts, the more sure it is that I shall run. Thus *imaginatio* alone is an impulse for my running."

p. 837: "*Imaginatio* used against me may be employed with such rigour, that I may be killed by the *imaginatio* of another person."

Vol. ii. p. 274: "Imagination comes from longing and desire: envy, hatred, proceed from longing, for they do not arise unless you long for them. As soon as you wish, the act of the imagination follows. This longing must be quick, ardent, lively, as that of a pregnant woman, &c. &c. — A general curse is commonly verified. Why? It comes from the heart, and the seed lies and is born in that coming from the heart. Thus parents' curses also come from the heart. The curse of the poor is likewise *imaginatio*. The prisoner's curse, also mere *imaginatio*, comes from the heart.... Thus too, when one man wishes to stab or paralyze, &c., another by means of his *imaginatio*, he must first attract the thing and instrument to himself and then he can impress it (with his wish): for whatever enters into it, may also go out of it again by the medium of thought as well as by that of the hands.... In such imagining, women outdo men ... for they are more ardent in revenge."

p. 298: "*Magica* is a great occult wisdom; just as Reason is a great, open folly.... No armour avails against sorcery, for it wounds the inner man, the vital spirit.... Some magicians make an image in the shape of a man they intend [to harm], knock a nail into the sole of its foot, and the man is invisibly struck with lameness, until the nail is removed."

p. 307: “We ought to know, that we may convey the spirit of any man into an image, solely by faith and by our strong imagination. — No incantation is needed, and the ceremonies, drawing of circles, fumigations, seals, &c. &c. are mere humbug to mislead. — *Homunculi* and images are made, &c. &c. ... by which all the operations, powers and will of man are carried out.... The human heart is indeed so great a thing, that no one can express it: as God is eternal and imperishable, so also is the heart of man. If we men thoroughly recognised our heart, nothing would be impossible for us on earth.... Perfect imagination, coming from the stars (*astris*) arises from the heart.”

p. 513: “*Imaginatio* is confirmed and rendered perfect by the belief that it really takes place: for every doubt injures the effect. Faith must confirm the imagination, for faith decides the will.... But just the fact that man does not always perfectly imagine, perfectly *believe*, causes acts to be called uncertain, which nevertheless may certainly and quite well exist.” A passage from Campanella’s book, “De sensu rerum et magia,” may serve to elucidate this last sentence. *Efficiunt alii ne homo possi futuere, si tantum credat: non enim potest facere quod non credit posse facere* (l. iv. c. 18).

Agrippa von Nettesheim[145] speaks in the same sense. “*Non minus subjicitur corpus alieno animo, quam alieno corpori*;” and:[146] “*Quidquid dictat animus fortissime odientis habet efficaciam nocendi et destruendi; similiter in ceteris, quæ affectat animus fortissimo desiderio. Omnia enim quæ tunc agit et dictat ex characteribus, figuris, verbis, gestibus et ejusmodi, omnia sunt adjuvantia appetitum animæ et acquirunt mirabiles quasdam virtutes, tum ab anima laborantis in illa hora, quando ipsum appetitus ejusmodi maxime invadit, tum ab influxa cœlesti animum tunc taliter movente.”*[147]— *“Inest hominum animis virtus quædam immutandi et ligandi res et homines ad id quod desiderat, et omnes res obediunt illi, quando fertur in magnum excessum alicujus passionis, vel virtutis, in tantum, ut superet eos, quos ligat. Radix ejusmodi ligationis ipsa est affectio animæ vehemens et exterminata.”*

And likewise Jul. Cæs. Vanninus, “De admir. naturæ arcan.” L. iv. dial. 5, § 435: “*Vehementem imaginationem, cui spiritus et sanguis obediunt, rem mente conceptam realiter efficere, non solum intra, sed et extra*.”[148]

Just so Joh. Bapt. Van Helmont, who takes great pains to explain away as much as possible of the Devil’s influence, in order to attribute it to the will.

I quote a few passages from the voluminous collection of his works, *Ortus Medicinæ*:

Recepta injecta. § 12. *Quum hostis naturæ (diabolus) ipsam applicationem complere ex se nequeat, suscitat ideam fortis desiderii et odii in saga, ut, mutuatis istis mentalibus et liberis mediis, transferat suum velle per quod quodque afficere intendit.*[149] *Quorsum imprimis etiam execrationes, cum idea desiderii et terroris, odiosissimis suis scrofis præscribit.* — § 13. *Quippe desiderium istud, ut est passio imaginantis, ita quoque creat ideam, non quidem inanem, sed executivam atque incantamenti motivam.* — § 19. *prout jam demonstravi, quod vis incantamenti potissima pendeat ab idea naturali sagæ.*

De injectis materialibus. § 15. *Saga, per ens naturale, imaginative format ideam liberam, naturalem et nocuam.... Sagæ operantur virtute naturali.... Homo etiam dimittit medium aliud executivum, emanativum et mandativum ad incantandum hominem; quod medium est Idea fortis desiderii. Est nempe desiderio inseparabile ferri circa optata.*

De sympatheticis mediis. § 2. *Ideæ scilicet desiderii, per modum influentiarum cœlestium, jaciuntur in proprium objectum, utcunque localiter remotum. Diriguntur nempe a desiderio objectum sibi specificante.*

De magnetica vulnerum curatione. § 76. *Igitur in sanguine est quædam potestas exstatica, quæ, si quando ardenti desiderio excita fuerit, etiam ad absens aliquod objectum, exterioris hominis spiritu deducenda sit: ea autem potestas in exteriori homine latet, velut in potentia; nec ducitur ad actum, nisi excitetur, accensa imaginatione ferventi desiderio, vel arte aliqua pari.* — § 98. *Anima, prorsum spiritus, nequaquam posset spiritum vitalem (corporeum equidem), multo minus carnem et ossa movere aut concitare, nisi vis illi quæpiam naturalis, magica tamen et spiritualis, ex anima in spiritum et corpus descenderet. Cedo, quo pacto obediret spiritus corporeus jussui animæ, nisi jussus spiritum, et deinceps corpus movendo foret? At extemplo contra hanc magicam motricem objicies, istam esse intra concretum sibi, suumque hospitium naturale, idcirco hanc etsi magam vocitemus, tantum erit nominis detorsio et abusus, siquidem vera et superstitiosa magica non ex anima basin desumit; cum eadem hæc nil quidquam valeat, extra corpus suum movere, alterare aut ciere. Respondeo, vim et magicam illam naturalem animæ, quæ extra se agat, virtute imaginis Dei, latere jam obscuram in homine, velut obdormire (post*

prævaricationem), excitationisque indigam: quæ eadem, utut somnolenta, ac velut ebria, alioqui sit in nobis quotidie: sufficit tamen ad obeunda munia in corpore suo: dormit itaque scientia et potestas magica, et solo nutu actrix in homine. — § 102. *Satan itaque vim magicam hanc excitat (secus dormientem et scientia exterioris hominis impeditam) in suis mancipiis, et inservit eadem illis, ensis vice in manu potentis, id est sagæ. Nec aliud prorsus Satan ad homicidium affert, præter excitationem dictæ potestatis somnolentæ.* — § 106. *Saga in stabulo absente occidit equum: virtus quædam naturalis a spiritu sagæ, et non a Satana, derivatur, quæ opprimat vel strangulet spiritum vitalem equi.* — § 139. *Spiritus voco magnetismi patronos, non qui ex cœlo demittuntur, multoque minus de infernalibus sermo est; sed de iis, qui fiunt in ipso homine, sicut ex silice ignis; ex voluntate hominis nempe aliquantillum spiritus vitalis influentis desumitur, et id ipsum assumit idealem entitatem, tanquam formam ad complementum. Qua nacta perfectione, spiritus mediam sortem inter corpora et non corpora assumit. Mittitur autem eo, quo voluntas ipsum dirigit; idealis igitur entitas ... nullis stringitur locorum, temporum aut dimensionum imperiis, ea nec dæmon est, nec ejus ullus effectus; sed spiritualis quædam est actio illius, nobis plane naturalis et vernacula.* — § 168. *Ingens mysterium propalare hactenus distuli, ostendere videlicet, ad manum in homine sitam esse energiam, qua, solo nutu et phantasia sua, queat agere extra se et imprimere virtutem aliquam, influentiam deinceps perseverantem, et agentem in objectum longissime absens.*

P. Pomponatius also says: *Sic contigit, tales esse homines, qui habeant ejusmodi vires in potentia, et per vim imaginativam et desiderativam cum actu operantur, tales virtus exit ad actum, et afficit sanguinem et spiritum, quæ per evaporationem petunt ad extra et producunt tales effectus*.[150]

Jane Leade, an English mystic visionary of Cromwell's time and pupil of Pordage, has given us some very curious disclosures of this kind. She is led to Magic in a very singular way. For, as the doctrine of their becoming one with the God of their religion is a fundamental characteristic of all Mystics, so is it with Jane Leade also. Now, with her however, the human will has its share in the omnipotence of the Divine will as a consequence of the two having become one, and accordingly acquires magic power. What other magicians therefore believe to be due to a compact with the Devil, she attributes to her becoming one with her God. Her Magic is therefore in the

highest sense ‘white Magic.’ Besides, this alters nothing as to the practice and results. She is reserved and mysterious, as people had to be in those times; still it is easy to see that the thing is not a mere theoretical corollary, but that it has sprung from knowledge and experience obtained in another way.

It is in her “Revelation of Revelations”[151] that we find the chief passage; but the following one, which is rather an abridgment than a literal quotation and is contained in Horst’s “Zauberbibliothek,”[152] comes from the same book: “Magic power enables its possessor to rule over and to renew the creation — *i.e.* the animal, vegetable and mineral kingdoms — so that, were *many* to co-operate in *one* magical power, Nature might be created anew as a paradise.... How is this magic power to be acquired? By renascence through faith: that is, by our *will* harmonizing with the divine *will*. For faith subjects the world to us, inasmuch as our own *will*, when it is in harmony with the divine *will*, results, as St. Paul tells us, in making everything submit to and obey us.” Thus far Horst. — p. 131 of the “Revelation, &c.,” Jane Leade shows that it was by the force of his will that Christ worked miracles, as, for instance, when he said to the leper: “I *will*; be thou clean.” Sometimes however he left it to the will of those who, he saw, believed in him, saying to them: “‘What *will* ye that I shall do unto you?’ in which cases no less was done for them than they had desired in their will that the Lord should do. These words of our Saviour’s are well deserving of notice, since the *highest Magia lies in the will*, so far as it is in union with the will of the Almighty: when these two wheels fit into each other, becoming in a sense *one*, they are, &c.” — Again, p. 132, she says: “For what could resist that which is united with the will of God? The power of such a will is so great, that it always achieves its end. It is no *naked will* deprived of its clothing, or power; on the contrary, it brings with it an irresistible omnipotence, which enables it to uproot, to plant, to put to death and to bring to life, to bind and to loose, to heal and to injure, which power will be collected and concentrated in its entirety in the royal, free-born will. Of this power we shall attain knowledge, when we shall have been made one with the Holy Ghost. or when we shall be united in one spirit and being.” — Again, p. 133: “We must quench or drown altogether the many multifarious wills which arise out of the mixed essence of souls, and they must lose themselves in the abysmal depth from which there will then arise and present itself the *virgin will*, which was never the slave of anything

belonging to degenerate man; on the contrary, it stands in connection with the Almighty Power, quite free and pure, and will infallibly produce fruits and results quite similar to those of the divine will ... wherefrom the burning oil of the Holy Ghost flows up in Magic, as it emits its fiery sparks."

Jacob Böhme too[153] speaks of Magic precisely in the sense here described. Among other things he says: "Magic is the mother of the essence of all beings: for it creates itself and is understood in *desire*.... True Magic is not a being, but the *desiring spirit* of the being. — In fine: Magic is action in the *will's spirit*."

In corroboration, or at any rate in explanation, of the above view of the will as the real agent in magic, a curious and interesting anecdote, related by Campanella, from Avicenna, may here find its place.[154] "*Mulieres quædam condixerunt, ut irent animi gratia in viridarium. Una earum non ivit. Ceteræ colludentes arangium acceperunt et perforabant eum stilis acutis, dicentes: ita perforamus mulierem talem, quæ nobiscum venire detrectavit, et, projecto arangio intra fontem, abierunt. Postmodum mulierem illam dolentem invenerunt, quod se transfigi quasi clavis acutis sentiret, ab ea hora, qua arangium ceteræ; perforarunt: et cruciata est valde donec arangii clavos extraxerunt imprecantes bona et salutem.*"

Krusenstern[155] gives a very curious and minute description of maleficent sorcery as practised, it is said successfully, by the priests of the savage tribes on the island of Nukahiva, the procedure in which is exactly similar to that of our cures by charms. — This fact is especially remarkable on account of the identity of the thing, notwithstanding the distance from all European tradition. With it ought to be compared Bende Bendsen's account of a headache he caused in another person by sorcery, through the medium of some of that person's hair which had been cut off. He concludes with the following words: "As far as I can learn, what is called witchcraft consists simply in preparing and applying noxious magnetic charms combined with a *maleficent influence of the will*: this is the detestable league with Satan."[156]

The agreement of all these writers, not only among themselves, but with the convictions to which Animal Magnetism has led in latter years, and finally even with what might be concluded from my speculative doctrine on this point, is surely a most remarkable phenomenon. This much is at any rate certain, that at the bottom of all the experiments, successful or unsuccessful, which have ever been made in Magic, there lies an

anticipation of my Metaphysic. For in them is expressed the consciousness, that the causal law only connects phenomena, while the inner nature of things remains independent of it; and also, that if any *direct* influence on Nature be possible from within, it can only take place through the *will* itself. But even if Magic were to be ranked as practical Metaphysic, according to Bacon's classification, it is certain that no other theoretical Metaphysic would stand in the right relation to it but mine, by which the world is resolved into Will and Representation.

The zealous cruelty with which Magic has always been persecuted by the Church and to which the papal *malleus maleficarum* bears terrible evidence, seems not to have for its sole basis the criminal purposes often associated with the practice of Magic or the part assumed to be played by the Devil, but rather to proceed partly from a vague foreboding and fear lest Magic should trace back its original power to its true source; whereas the Church has assigned to it a place outside Nature.[157] The detestation shown by the cautious clergy of England towards Animal Magnetism[158] tends to confirm this supposition, and also the active zeal with which they oppose table-turning, which at any rate is harmless, yet which, for the same reason, has been violently assailed by the anathemas of the French, and even of the German, clergy.[159]

SINOLOGY.

Nothing perhaps points more directly to a high degree of civilization in China than the almost incredible density of its population, now rated, according to Gützlaff, at 367 millions of inhabitants.[160] For whether we compare countries or ages, we find on the whole that civilization keeps pace with population.

The pertinacious zeal with which the Jesuit missionaries of the seventeenth and eighteenth centuries strove to inculcate their own relatively new doctrines into the minds of this very ancient nation, and their futile endeavours to discover early traces of their own faith in that country, left them no time for a profound study of the belief which prevails there. Therefore Europe has only lately obtained some slight knowledge of the religious state of the Chinese. We now know, that is to say, that in China there exists first of all a worship of Nature, which is universally professed, and dates from the earliest times, even, it is alleged, from before the discovery of fire, wherefore animals were sacrificed raw. The sacrifices offered up publicly at certain seasons or after great events by the Chinese Emperor and the chief dignitaries of the Empire, belong to this worship. These sacrifices are dedicated first and foremost to the blue sky and to the earth — to the blue sky in the winter solstice, to the earth in the summer solstice — and, after these, to every possible power of Nature: the sea, mountains, rivers, winds, thunder, rain, fire, &c. &c. A genius presides over each of these, and each genius has several temples. On the other hand, each genius presiding over every single province, town, village, or street, nay over family funerals and even sometimes over a merchant's warehouse, has also temples; only, in the two last cases they are destined exclusively for private worship. But public worship is besides offered up to former illustrious Emperors, founders of dynasties and to heroes, *i.e.* to all such as have benefited (Chinese) mankind by word or deed. Even these have their temples: Confucius alone having no less than 1,650 dedicated to him. This therefore accounts for the great number of small temples found throughout the Empire. With this hero-worship too, is associated the private worship offered up by every respectable family on the tombs of their ancestors. — Now besides this worship of Nature and of heroes, which is universal, there are three other prevailing religious doctrines in China, more with a

dogmatical intent. First among these is the doctrine of Taossee, founded by Laotse, an older contemporary of Confucius. This is the doctrine of Reason, as the inner order of the Universe or inherent principle of all things, of the great One, the sublime Gable-Beam (Taiki) which supports all the Rafters, yet is above them (properly the all-pervading Soul of the World) and of Tao, *i.e.* the *Way*, namely to salvation: that is, to redemption from the world and its misery. We have an exposition of this doctrine taken from the fountain-head in Stanislas Julien's translation (1842) of Laotse's Taoteking, in which we find that the Tao-doctrine completely harmonizes with Buddhism both in meaning and in spirit. This sect however seems to have fallen very much into the background, and its teachers to be now looked down upon. — Secondly, we find the wisdom of Confucius, which has special attractions for Chinese *savants* and statesmen. Judging from translations, it is a rambling, commonplace, predominantly political, moral philosophy, without any metaphysical support, which has something peculiarly insipid and tiresome about it. — Finally, there exists for the bulk of the nation Buddha's sublime doctrine full of love. The name, or rather title, of Buddha in China is *Fo* or *Fhu*, whilst in Tartary the "Victoriously-Perfect" is more frequently called by his family-name, *Shakia-Muni*, and also *Burkhan-Bakshi*; in Birma and Ceylon, he is generally called *Gótama* or *Tagátata*, but his original name was Prince *Siddharta*.[161] This religion which, on account of its intrinsic excellence and truth, as well as of the great number of its followers, may be considered as ranking highest among all religions on earth, prevails throughout the greater part of Asia, and according to the latest investigator, Spence Hardy, numbers 369 millions of believers: that is, far more than any other. — These three religions, the most widely diffused of which, Buddhism, subsists without any protection whatever from the State, by its own power alone — a circumstance which speaks greatly in its favour — are far from being hostile to one another, and exist quietly side by side, nay, harmonize even to a certain extent, perhaps by reciprocal influence, so that the sentence: "The three doctrines are only one", has become proverbial. The Emperor, as such, professes all three; still many of the Emperors, even up to the most recent times, have been especially devoted to Buddhism. This is shown by their profound respect for the Dalaï-Lama, nay, even for the Teshoo-Lama, to whom they unhesitatingly yield precedence. — These three religions are neither monotheistic nor polytheistic, nor are they even pantheistic — Buddhism, at

any rate, is not; since Buddha did not look upon a world sunk in sin and suffering, whose tenants, all subject to death, only subsist for a short time by devouring each other, as a manifestation of God. Moreover the word Pantheism, properly speaking, contains a contradiction; for it denotes a self-destroying conception, and has therefore never been understood otherwise than as a polite term of expression by those who know what seriousness means. It accordingly never entered into the heads of the clever, acute philosophers of the eighteenth century, not to take Spinoza for an Atheist, on account of his having called the world Deus; on the contrary, this discovery was reserved for the sham philosophers of our own times, who know nothing but words: they even pique themselves on the achievement and accordingly talk about Acomism, the wags! But I would humbly suggest leaving their meanings to words — in short, calling the world, the world; and gods gods.

In their endeavours to acquire knowledge of the state of Religion in China, Europeans began as usual, and as the Greeks and Romans under similar circumstances had done, by first searching for points of contact with their own belief. Now as, in their own way of thinking, the conceptions of Religion and of Theism were almost identified, or at any rate had grown together so closely, that they could only be separated with great difficulty; as moreover, till a more accurate knowledge of Asia had reached Europe, the very erroneous opinion had been disseminated — for the purpose of argument *e consensu gentium* — that all nations on earth worship a single, or at any rate a highest, God, Creator of the Universe:[162] when they found themselves in a country where temples, priests and monasteries abounded, they started from the firm assumption that Theism would also be found there, though in some very unusual form. On seeing these expectations disappointed however, and on finding that the very conceptions of such things, let alone the words to express them, were unknown, it was but natural, considering the spirit in which their inquiries were made, that their first reports of these religions should refer rather to what they did not, than to what they did, contain. Besides, for many reasons, it can be no easy task for European heads to enter fully into the sense of these faiths. In the first place, they are brought up in Optimism, whereas in Asia, existence itself is looked upon as an evil and the world as a scene of misery, where it were better not to find oneself. Another reason is to be found in the decided Idealism which is essential to Buddhism and to Hindooism: a view only

known in Europe as a paradox hardly worth a serious thought, advanced by certain eccentric philosophers; whereas in Asia it is even embodied in popular belief. For in Hindoostan it prevails universally as the doctrine of *Maja*, and in Thibet, the chief seat of the Buddhist Church, it is taught in an extremely popular way, a religious comedy being performed on occasions of special solemnity, in which the Dalaï-Lama is represented arguing with the Arch-fiend. The former defends Idealism, the latter Realism, and among other things the Devil says: "What is perceived through the five sources of all knowledge (the senses), is no deception, and what you teach is not true." After a long argumentation the matter is decided by a throw of the dice: the Realist (the Devil) loses, and is dismissed amid general jeering.[163] Keeping this fundamental difference in the whole way of thinking steadily in view, we shall find it not only excusable, but even natural, that in their investigation of the Asiatic religions Europeans should at first have stopped short at the negative stand-point; though, properly speaking, it has nothing to do with the matter. We therefore find a great deal referring to this negative stand-point which in no way advances our positive knowledge; it all however amounts to this: that Monotheism — an exclusively Jewish doctrine, to be sure — is alien to Buddhists and in general to the Chinese. For instance, in the "Lettres Édifiantes"[164] we find: "The Buddhists, whose views on the migration of souls are universally adopted, are accused of Atheism." In the "Asiatic Researches" (vol. vi. p. 255) we find: "The religion of the Birmans (Buddhism) shows them to be a nation far advanced beyond the barbarism of a wild state and greatly influenced by religious opinions, but which nevertheless has no knowledge of a Supreme Being, Creator and Preserver of the world. Yet the system of morality recommended in their fables is perhaps as good as any other taught by the religious doctrines which prevail among mankind." — And again, p. 258: "The followers of Gótama (*i.e.* of Buddha) are strictly speaking Atheists." — *Ibid.*, p. 258: "Gótama's sect consider the belief in a divine Being, Creator of the world, to be highly impious." — *Ibid.*, p. 268, Buchanan relates, that Atuli, the Zarado or High-Priest of the Buddhists at Ava, in an article upon his religion which he presented to a Catholic bishop, "counted the doctrine, that there is a Being who has created the world and all things in it and is alone worthy of adoration, among the six damnable heresies." Sangermano relates precisely the same thing,[165] and closes the list of the six grave heresies with the words: "The last of these impostors taught, that

there is a Supreme Being, the Creator of the world and of all things in it, and that he alone is worthy of adoration.” Colebrooke too says:[166] “The sects of Jaina, and Buddha are really atheistic, for they acknowledge no Creator of the world, nor any Supreme ruling Providence.” — I. J. Schmidt[167] likewise says: “The system of Buddhism knows no eternal, uncreated, single, divine Being, having existed before all Time, who has created all that is visible and invisible. This idea is quite foreign to Buddhism and there is not the slightest trace of it anywhere in Buddhistic books.” — We find the learned sinologist Morrison too[168] not less desirous to discover traces of a God in the Chinese dogmas and ready to put the most favourable construction upon everything which seems to point in that direction; yet he is finally obliged to own that nothing of the kind can be clearly discovered. Where he explains the words *Thung* and *Tsing*, *i.e.* repose and movement, as that on which Chinese cosmogony is based, he renews this inquiry and concludes it with the words: “It is perhaps impossible to acquit this system of the accusation of Atheism.” — And even recently Upham[169] says: “Buddhism presents to us a world without a moral ruler, guide or creator.” The German sinologist Neumann too, says in his treatise[170] mentioned further on: “In China, where neither Mahometans nor Christians found a Chinese word to express the theological conception of the Deity.... The words God, soul, spirit, as independent of Matter and ruling it arbitrarily, are utterly unknown in the Chinese language.... This range of ideas has become so completely one with the language itself, that the first verse of the book of Genesis cannot without considerable circumlocution be translated into genuine Chinese.” — It was this very thing that led Sir George Staunton to publish a book in 1848 entitled: “An Inquiry into the proper mode of rendering the word God in translating the Sacred Scriptures into the Chinese language.”[171]

My intention in giving the above quotations and explanations, is merely to prepare the way for the extremely remarkable passage, which it is the object of the present chapter to communicate, and to render that passage more intelligible to the reader by first making him realize the standpoint from which these investigations were made, and thus throwing light upon the relation between them and their subject. For Europeans, when investigating this matter in China in the way and in the spirit described, always inquiring for the supreme principle of all things, the power that rules the world, &c. &c., had often been referred to that which is designated by

the word Tien (Engl. T'hëen). Now, the more usual meaning of this word is "Heaven," as Morrison also says in his dictionary; still it is a well-known thing that Tien is used in a figurative sense also, and then has a metaphysical signification. In the "Lettres Édifiantes"[172] we find the following explanation: "*Hing-tien* is the material, visible heaven; *Chin-tien* the spiritual and invisible heaven." Sonnerat too,[173] in his travels in East-India and China, says: "When the Jesuits disputed with the rest of the missionaries as to the meaning of the word Tien, whether it was Heaven or God, the Chinese looked upon these foreigners as restless folk and drove them away to Macao." It was at any rate through this word that Europeans could first hope to find the track of that Analogy of Chinese Metaphysic with their own faith, which had been so persistently sought for; and it was doubtless owing to investigations of this kind that the results we find communicated in an Essay entitled "Chinese Theory of the Creation" were attained.[174] As to *Choo-foo-tze*, called also *Choo-hi*, who is mentioned in it, I observe that he lived in the twelfth century according to our chronology, and that he is the most celebrated of all the Chinese men of learning; because he has collected together all the wisdom of his predecessors and reduced it to a system. His work is in our days the basis of all Chinese instruction, and his authority of the greatest weight. In the passage I allude to, we find: "The word *Teen*, would seem to denote 'the highest among the great' or 'above all what is great on earth:' but in practice its vagueness of signification is beyond all comparison greater, than that of the term *Heaven* in European languages.... Choo-foo-tze tells us that 'to affirm, that heaven has a *man* (*i.e.* a sapient being) there to judge and determine crimes, should not by any means be said; nor, on the other hand, must it be affirmed, that there is nothing at all to exercise a supreme control over these things.'

"The same author being asked about the *heart of heaven*, whether it was intelligent or not, answered: it must not be said that the mind of nature is unintelligent, but it does not resemble the cogitations of man....

"According to one of their authorities, *Teen* is call'd ruler or sovereign (Choo), from the idea of the supreme control, and another expresses himself thus: Had heaven (Teen) no designing mind, then it must happen, that the cow might bring forth a horse, and on the peach-tree be produced the blossom of the pear.' On the other hand it is said, that *the mind of Heaven is deducible from what is the Will of mankind*!"

The agreement between this last sentence and my doctrine is so striking and so astonishing, that if this passage had not been printed full eight years after my own work had appeared, I should no doubt have been accused of having taken my fundamental thought from it. For there are three well-known modes of repelling the attack of new thoughts: firstly, by ignoring them, secondly by denying them, and lastly by asserting that they are not new, but were known long before. But the fact that my fundamental thought was formed quite independently of this Chinese authority, is firmly established by the reasons I have given; for I may hope to be believed when I affirm, that I am unacquainted with the Chinese language and consequently unable to derive thoughts for my own use from original Chinese sources unknown to others. On further investigation I have elicited the fact, that the passage I have quoted, was most probably, nay almost certainly, taken from Morrison's "Chinese Dictionary," where it may be found under the sign *Tëen:* only I have no opportunity of verifying it.[175] — In an article by Neumann[176] there are some passages which have evidently a common source with those here quoted from the "Asiatic Journal." But they are written with the vagueness of expression which is so frequent in Germany, and excludes clear comprehension. Besides, this translator of Choo-hi evidently did not himself quite understand the original; though by this no blame need be implied, when we consider the enormous difficulty of the Chinese language for Europeans, and the insufficiency of the means for studying it. Meanwhile it does not give us the enlightenment desired. We must therefore console ourselves with the hope, that as a freer intercourse with China has now been established, some Englishman may one day give us more minute and thorough information concerning the above-mentioned dogma, of which we have hitherto received such deplorably imperfect accounts.

REFERENCE TO ETHICS.

For reasons I have stated in the beginning, confirmations of the rest of my doctrine are excluded from my present task. Still, in concluding, I may perhaps be allowed to make a general reference to Ethics.

From time immemorial, all nations have acknowledged that the world has a moral, as well as a physical, import. Everywhere nevertheless the matter was only brought to an indistinct consciousness, which, in seeking for its adequate expression, has clothed itself in various images and myths. These are the different Religions. Philosophers, on their side, have at all times endeavoured to attain clear comprehension of the thing and, notwithstanding their differences in other respects, all, excepting the strictly materialistic, philosophical systems, agree in this one point: that what is most important, nay, alone essential, in our whole existence, that on which everything depends, the real meaning, pivot or point (*sit venia verbo*) of it, lies in the morality of human actions. But as to the sense of this, as to the ways and means, as to the possibility of the thing, they all again quite disagree, and find themselves before an abyss of obscurity. Thus it follows, that it is easy to preach, but difficult to found, morality. It is just because that point is determined by our conscience, that it becomes the touchstone of all systems; since we demand, and rightly demand, that Metaphysic should give support to Ethics: and now arises the difficult problem to show that, contrary to all experience, the physical order of things depends upon a moral one, and to find out a connection between the force which, by acting according to eternal laws of Nature, gives the world stability, and the morality which has its seat in the human breast. This is therefore the rock on which the best thinkers have foundered. Spinoza occasionally tacks a moral theory on to his Pantheistic Fatalism by means of sophisms, but more often leaves morality terribly in the lurch. Kant, when theoretical Reason is exhausted, sends his Categorical Imperative, laboriously worked out of mere conceptions,[177] on the stage, as *deus ex machina*, with an absolute *ought*. But the mistake he made by it only became quite clear when Fichte, who always took outbidding for outdoing, had spun it out with Christian Wolfian prolixity and wearisomeness to a complete system of *moral fatalism* in his “System of Moral Doctrine,” and subsequently presented it more briefly in his last pamphlet.[178]

Now, from this point of view, a system which places the reality of all existence and the root of the whole of Nature in *the Will*, and in this will places the root of the world, must undeniably carry with it, to say the least, a strong prejudice in its favour. For, by a direct and simple way, it reaches, nay, already holds in its hand before coming to Ethics, what other systems try to reach by roundabout, ever dubious by-paths. Nor indeed can any other road ever lead to this but the insight, that the active and impulsive force in Nature which presents this perceptible world to our intellect, is identical with the will within us. The only Metaphysic which really and immediately supports Ethics, is that one which is itself primarily ethical and constituted out of the material of Ethics. Therefore I had a far greater right to call my Metaphysic "Ethics," than Spinoza, with whom the word sounds almost like irony, and whose "Ethics" might be said to bear the name like *lucus a non lucendo*; since it is only by means of sophistry that he has been able to tack his morality on to a system, from which it would never logically proceed. In general, moreover, he disavows it downright with revolting assurance.[179] On the whole, I can confidently assert, that there has never yet been a philosophical system so entirely cut out of one piece, so completely without any joins or patches, as mine. As I have said in my preface, it is the unfolding of a single thought, by which the ancient ἁπλοῦς ὁ μῦθος τῆς ἁληθείας ἔφυ[180] is again confirmed. Then we must still take into consideration here, that freedom and responsibility — those pillars on which all morality rests — can certainly be asserted in words without the assumption of the aseity[181] of the will; but that it is absolutely impossible to think them without it. Whoever wishes to dispute this, must first invalidate the axiom, stated long ago by the Schoolmen: *operari sequitur esse* (*i.e.* the acts of each being follow from the nature of that being), or we must demonstrate the fallacy of the inference to be drawn from it: *unde esse, inde operari*. Responsibility has for its condition freedom; but freedom has for its condition primariness. For I *will* according to what I *am*; therefore I must *be* according to what I *will*. Aseity of the will is therefore the first condition of any Ethics based on serious thought, and Spinoza is right when he says: *Ea res libera dicetur, quæ ex sola suæ naturæ necessitate* existit, *et a se sola ad agendum determinatur*.[182] Dependence, as to existence and nature, united with freedom as to action, is a contradiction. Were Prometheus to call the creatures of his making to account for their actions, they would be

quite justified in answering: "We could only act according to our being: for actions arise from nature. If our actions were bad, the fault lay in our nature: this is thine own work; punish thyself."[183] And it is just the same with the imperishableness of our true being in death; for this cannot be seriously thought without the aseity of that being, and can even hardly be conceived without a fundamental separation of the will from the intellect. This last point is peculiar to my philosophy; but Aristotle had already proved the first thoroughly, by showing at length how that alone can be imperishable which has not arisen, and that the two conceptions condition each other:[184] Ταῦτα ἀλλήλοις ἀκολουθεῖ, καὶ τό τε ἀγένητον ἄφθαρτον, καὶ τὸ ἄφθαρτον ἀγένητον.... τὸ γὰρ γενητὸν καὶ τὸ φθαρτὸν ἀκολουθοῦσιν ἀλλήλοις. — εἰ γενητόν τι, φθαρτὸν ἀνάγκη[185] (*hæc mutuo se sequuntur, atque ingenerabile est incorruptibile, et incorruptibile ingenerabile.... generabile enim et corruptibile mutuo se sequuntur. — si generabile est, et corruptibile esse necesse est*). All those among the ancient philosophers who taught an immortality of the soul, understood it in this way; nor did it enter into the head of any of them to assign infinite permanence to a being *having arisen* in any way. We have evidence of the embarrassment to which the contrary assumption leads, in the ecclesiastical controversy between the advocates of Pre-existence, Creation and Traduction.

The Optimism moreover of all philosophical systems is a point closely allied to Ethics which must never fail in any of them, as in duty bound: for the world likes to hear that it is commendable and excellent, and philosophers like to please the world. With me it is different: I have seen what pleases the world, and therefore shall not swerve a step from the path of truth in order to please it. Thus in this point also my system varies from all the others and stands by itself. But when all the others have completed their demonstrations to the song of the best of worlds, quite at the last, at the background of the system, like a tardy avenger of the monster, like a spirit from the tomb, like the statue in Don Juan, there comes the question as to the origin of evil, of the monstrous, nameless evil, of the awful, heartrending misery in the world: — and here they are speechless, or can only find words, empty, sonorous words, with which to settle this heavy reckoning. On the other hand, a system, in whose basis already the existence of evil is interwoven with the existence of the world, need not fear that apparition any more than a vaccinated child need fear the smallpox. Now this is the case when freedom is placed in the *esse* instead of in the

operari and sin, evil and the world then proceed from that *esse*. — Moreover it is fair to let me, as a serious man, only speak of things which I really know and only make use of words to which I attach a quite definite meaning; since this alone can be communicated with security to others, and Vauvenargues is quite right in saying: "*la clarté est la bonne foi des philosophes*." Therefore if I use the words 'Will, Will to live,' this is no mere *ens rationis*, no hypostasis set up by me, nor is it a term of vague, uncertain meaning; on the contrary, I refer him, who asks what it is, to his own inner self, where he will find it entire, nay, in colossal dimensions, as a true *ens realissimum*. I have accordingly not explained the world out of the unknown, but rather out of that which is better known than anything, and known to us moreover in quite a different way from all the rest. As to the paradoxical character finally, with which the ascetic results of my Ethics have been reproached, these results had given umbrage even to Jean Paul, otherwise so favourably disposed towards me, and had induced Herr Rätze also (not knowing that the only course to be adopted against me was silence) to write a book against me in 1820, with the best intentions. They have since become the standing rock of offence in my philosophy; but I beg my readers to take into consideration, that it is only in this north-western portion of the ancient continent, and even here only in Protestant countries, that the term paradoxical can be applied to such things; whereas throughout the whole of vast Asia — everywhere indeed, where the detestable doctrine of Islam has not prevailed over the ancient and profound Religions of mankind by dint of fire and sword — they would rather have to fear the reproach of being commonplace. I console myself therefore with the thought that, when referred to the Upanishads of the Sacred Vedas, my Ethics are quite orthodox,[186] and that even with primitive, genuine Christianity they stand in no contradiction. As to all other accusations of heresy, I am well armoured and my breast is fortified with triple steel.

CONCLUSION.

The undoubtedly striking confirmations recorded in this treatise, which have been contributed to my doctrine by the Empirical Sciences since its first appearance, but independently of it, will unquestionably have been followed by many more: for how small is the portion which the individual can find time, opportunity and patience to become acquainted with, of the branch of literature dedicated to Natural Science which is so actively cultivated in all languages! Even what I have here mentioned however, inspires me with confidence that the time for my philosophy is ripening; and it is with heartfelt joy that I see the Empirical Sciences gradually come forward in the course of time, as witnesses above suspicion, to testify to the truth of a doctrine, concerning which a politic, inviolable silence has been maintained for seventeen years by our "philosophers by profession" (some of them give themselves this characteristic name, nay even that of "philosophers by trade"); so that it had been left to Jean Paul, who was ignorant of their tactics, to draw attention to it. For it may have appeared to them a delicate matter to praise it, and, on due consideration, they may have thought it not altogether safe to blame it either, and may have judged it unnecessary besides to show the public, as belonging neither to the profession nor to the trade, that it is quite possible to philosophize very seriously without being either unintelligible or wearisome. Why compromise themselves therefore with it, since no one betrays himself by silence and the favourite secretive method was ready at hand, the approved specific against merit; this much was besides soon agreed upon: that, considering the circumstances of the times, my philosophy did not possess the right qualifications for being taught professionally. Now the true, ultimate aim of all philosophy, with them, is to be taught professionally, — so much and so truly is it so, that were Truth to come down stark naked from lofty Olympus, but were what she brought with her not found to correspond to the requirements called for by the circumstances of the times, or to the purposes of their mighty superiors, these gentlemen "of the profession and trade" would verily waste no time with the indecent nymph, but would hasten to bow her out again to her Olympus, then place three fingers on their lips and return quietly to their compendia. For assuredly he who makes love to this nude beauty, to this fascinating syren, to this

portionless bride, will have to forego the good fortune of becoming a Government and University professor. He may even congratulate himself if he becomes a garret-philosopher. On the other hand, his audience will consist, not of hungry undergraduates anxious to turn their learning to account, but rather of those rare, select thinkers, thinly sprinkled among the countless multitude, who arise from time to time, almost as a freak of Nature. And a grateful posterity is beckoning from afar. But they can have no idea of the beauty and loveliness of Truth, of the delight there is in pursuing her track, of the rapture in possessing her, who can imagine that anyone who has once looked her in the face can ever desert, deny, or distort her for the sake of the venal approval, of the offices, of the money or the titles of such people. Better to grind spectacle-glasses like Spinoza or draw water like Cleanthes. Henceforth they may take whatever course they like: Truth will not change her nature to accommodate "the trade." Serious philosophy has now really outgrown Universities, where Science stands under State-guardianship. It may however some day perhaps come to be counted among the occult sciences; while the spurious kind, that *ancilla theologiæ* in Universities, that inferior counterfeit of Scholasticism, for which the highest criterion of philosophical truth lies in the country catechism, will make our Lecture-halls doubly re-echo.— "You, that way: we, this way." — [187]

ENDNOTES.

[1] And this infatuation has reached such a point, that people seriously imagine themselves to have found the key to the mystery of the essence and existence of this wonderful and mysterious world in wretched *chemical affinities*! Compared with this illusion of our physiological chemists, that of the alchymists who sought after the philosopher's stone, and only hoped to find out the secret of making gold, was indeed a mere trifle. [Add. to 3rd ed.]

[2] "*Aut catechismus, aut materialismus*," is their watchword. [Add. to 3rd ed.]

[3] There too he will meet with people who fling about words of foreign origin, which they have caught up without understanding them, just as readily as he does himself, when he talks about "*Idealism*" without knowing what it means, mostly therefore using the word instead of Spiritualism (which being Realism, is the opposite to Idealism). Hundreds of examples of this kind besides other *quid pro quos* are to be found in books, and critical periodicals. [Add. to 3rd ed.]

[4] They ought everywhere to be shown that their belief is not believed in. [Add. to 3rd ed.]

[5] For revelation goes for nothing in philosophy; therefore a philosopher must before all things be an unbeliever. [Add. to 3rd ed.].

[6] One always says the other is right, so that the public in its simplicity at last imagines them really to be right. [Add. to 3rd ed.]

[7] Here it is especially Ernst Reinhold's "System of Metaphysics" (3rd edition, 1854) that I have in my eye. In my "Parerga" I have explained how it comes, that brain-perverting books like this go through several editions. See "Parerga," vol. i. p. 171 (2nd edition, vol. i. p. 194).

[8] Nevertheless, by Zeus, all such gentlemen, in France as well as Germany, should be taught that Philosophy has a different mission from that of playing into the hands of the clergy. We must let them clearly see before all things that we have no faith in their faith — from this follows what we think of them. [Add. to 3rd ed.]

[9] (*a*) Rosenkranz, "Meine Reform der Hegelschen Philosophie," 1852, especially p. 41, in a pompous, dictatorial tone: "I have explicitly said, that Space and Time would not exist if Matter did not exist. Æther spread out within itself first constitutes real Space, and the movement of this æther and consequent real genesis of everything individual and separate, constitutes real Time." (*b*) L.

Noack, “Die Theologie als Religionsphilosophie,” 1853, pp. 8, 9. (*c*) V. Reuchlin-Meldegg, Two reviews of Oersted’s “Geist in der Natur” in the Heidelberg Annals, Nov.-Dec., 1850, and May-June, 1854.

[10] Time is the condition of the *possibility* of succession, which could neither take place, nor be understood by us and expressed in words, without Time. And Space is likewise the condition of the *possibility* of juxtaposition, and Transcendental Æsthetic is the proof that these conditions have their seat in the constitution of our head. [Add. to 3rd ed.]

[11] In the Scholium to the eighth of the definitions he has placed at the top of his “Principia,” Newton quite rightly distinguishes *absolute*, that is, *empty*, from relative, or filled Time, and likewise absolute from relative Space. He says, p. 11: *Tempus, spatium, locum, motum, ut omnibus notissima, non definio. Notandum tamen quod* VULGUS (that is, professors like those I have been mentioning) *quantitates hasce non aliter quam ex relatione ad sensibilia concipiat. Et inde oriuntur præjudicia quædam, quibus tollendis convenit easdem in absolutas et relativas, veras et apparentes, mathematicas et vulgares distingui.* And again (p. 12):

I. *Tempus absolutum, verum et mathematicum, in se et natura sua sine relatione ad externum quodvis, æquabiliter fluit, alioque nomine dicitur Duratio: relativum, apparens et vulgare est sensibilis et externa quævis Durationis per motum mensura (seu accurata seu inæquabilis) quâ vulgus vice veri temporis utitur; ut Hora, Dies, Mensis, Annus.*

II. *Spatiam absolutum, natura sua sine relatione ad externum quodvis, semper manet similare et immobile: relativum est spatii hujus mensura seu dimensio quælibet mobilis, quæ a sensibus nostris per situm suum ad corpora definitur, et a vulgo pro spatio immobili usurpatur: uti dimensio spatii subterranei, ærei vel coelestis definita per situm suum ad terram.*

But even Newton never dreamt of asking how we know these two infinite entities, Space and Time; since, as he here impresses on us, they do not fall within the range of the senses; and how we know them moreover so intimately, that we are able to indicate their whole nature and rule down to the minutest detail. [Add. to 3rd ed.]

[12] Ecclesiasticus xxii. 8.

[13] For Kant has disclosed the dreadful truth, that philosophy must be quite a different thing from Jewish mythology. [Add. to 3rd ed.]

[14] Another instance of Michelet's ignorance is to be found in Schopenhauer's posthumous writings, see "Aus Arthur Schopenhauer's handschriftlichem Nachlass," Leipzig, A. Brockhaus, 1864, p. 327. [Editor's note.]

[15] The same reviewer (Von Reuchlin-Meldegg) when be expounds the doctrines of the philosophers concerning God in the August number of the Heidelberg Annals (1855), p. 579, says: "In Kant, God is a thing in itself which cannot be known." In his review of Frauenstädt's "Letters" in the Heidelberg Annals of May and June (1855) he says that there is no knowledge *à priori*. [Add. to 3rd ed.]

[16] C. 1. p. 899.

[17] p. 908.

[18] *Hofräthe.* A title of honour often given for literary and scientific merit in Germany, and common among University professors. [Tr.'s note.]

[19] "*Potius de rebus ipsis judicare debemus, quam pro magno habere, de hominibus quid quisque senserit scire*," says St. Augustine ("*De civ. Dei*," l. 19, c. 3). Under the present mode of proceeding, however, the philosophical lecture-room becomes a sort of rag-fair for old worn out, cast-off opinions, which are brought there every six months to be aired and beaten. [Add. to 3rd ed.]

[20] I take this opportunity urgently to request that the public will not believe unconditionally any accounts of what I am supposed to have said, even when they are given as quotations; but will first verify the existence of these quotations in my works. In this way many a falsehood will be detected, which can however only be stamped as a direct forgery when accompanied by quotation marks (" "). [Add. to 3rd ed.]

[21] "Die Welt a. W. u. V.," vol. ii., c. 18, p. 213.

[22] So had I written in 1835, when the present treatise was first composed, having published nothing since 1818, before the close of which year "Die Welt als Wille und Vorstellung" had appeared. For a Latin version, which I had added to the third volume of "*Scriptores ophthalmologici minores*," *edente* J. Radio, in 1830, for the benefit of my foreign readers, of my treatise "On Vision and Colours" (published in 1816), can hardly be said to break the silence of that pause.

[23] As will be seen by the following detailed exposition, Schopenhauer attaches a far wider meaning to the word than is usually given, and regards the *will*, not merely as *conscious volition* enlightened

by Reason and determined by motives, but as the fundamental essence of all that occurs, even where there is no choice. [Tr.]

[24] Kant, “Von der wahren Schätzung der lebendigen Kräfte,” § 51.

[30] Göthe, “Tag und Jahreshefte,” 1812.

[31] This I wrote in 1836. The “Edinburgh Review” has since however greatly deteriorated, and is no longer its old self. I have even seen clerical time-serving in its pages, written down to the level of the mob.

[32] As a being existing by itself, a thing in itself. [Add. to 3rd ed.]

[33] In which it is lodged in the garret. [Add. to 3rd ed.]

[34] By this Schopenhauer means the distinction between *the will* in its widest sense, regarded as the fundamental essence of all that happens, — even where there is no choice, even where it is *unconscious*, — and *conscious will*, implying deliberation and choice, commonly called *free-will*. We must however carefully guard against confounding this *relative* free-will, with *absolute* free-will (*liberum arbitrium indifferentiæ*), which Schopenhauer declares to be inadmissible. The sense in which I have used the expression ‘*free-will*’ throughout this treatise, is that of *relative* freedom, *i.e.* power to choose between different motives, free of all outward restraint (*Willkühr*). (Tr.)

[35] I have shown the difference between *cause* in its narrowest sense, *stimulus*, and *motive*, at length in my “Grund-probleme der Ethik” p. 29 *et seq.*

[36] It is especially in secretive processes that we cannot avoid recognising a certain selection of the materials fitted for each purpose, consequently a *free will* in the secretive organs, which must even be

assisted by a certain dull sensation, and in virtue of which each secreting organ only extracts from the same blood that particular secretion which suits it and no others: for instance, the liver only absorbs bile from the blood flowing through it, sending the rest of the blood on, and likewise the salivary glands and the pancreas only secrete saliva, the kidneys only urine, &c. &c. We may therefore compare the organs of secretion to different kinds of cattle grazing on one and the same pasture-land, each of which only browses upon the one sort of herb which suits its own particular appetite. [Add. to 3rd ed.]

[51] The Matsya Parana attributes a similar origin to Brahma's four countenances. It relates that, having fallen in love with his daughter Satarupa, and gazed fixedly at her, she stepped aside to avoid his eye; he being ashamed, would not follow her movement; whereupon a new face arose on him directed towards the side where she was and, on her once more moving, the same thing occurred, and was repeated, until at last he had four faces. ("Asiatic Researches," vol. 6, p. 473.) [Add. to 3rd ed.]

[52] I should like under this name to add a fourth to the three proofs brought forward by Kant, *i.e.* the proof *a terrore*, which the ancient saying of Petronius: *primus in orbe Deos fecit timor*, designates and of which Hume's incomparable "Natural History of Religion" may be considered as the critique. Understood in this sense, even the theologist Schleiermacher's attempted proof might have its truth from the feeling of dependence, though perhaps not exactly that truth which its originator imagined it to have.

[53] Socrates propounded it already in detail in Xenophon. ("Mem." i. 4.) [Add. to 3rd ed.]

[57] The point at which the life-spark is kindled. [Tr.]

[58] Nor can a *mundus intelligibilis* precede a *mundus sensibilis*; since it receives its material from the latter alone. It is not an intellect which has brought forth Nature; it is, on the contrary, Nature which has brought forth the intellect. [Add. to 3rd ed.]

[59] This is expanded, vol. iv. pp. 825-843.

[60] I have seen (Zooplast. Cab. 1860) a humming-bird (*colibri*) with a beak as long as the whole bird, head and tail included. This bird must certainly have had to fetch out its food from a considerable depth, were it only from the calyx of a flower (Cuvier, "Anat. Comp." vol. iv. p. 374); otherwise it would not have given itself the luxury, or submitted to the encumbrance, of such a beak.

[66] *Urthier.*

[67] Animated by the feeling of this truth, Robert Owen, after passing in review the numerous and often very large Australian fossile *marsupialia* — sometimes as big as the rhinoceros — came as early as 1842 to the conclusion, that a large beast of prey must have contemporaneously existed. This conclusion was afterwards confirmed, for in 1846 he received part of the fossile skull of a beast of prey of the size of the lion, which he named *thylacoleo*, *i.e.* lion with a pouch, since it is also a marsupial. (See the "Times" of the 19th of May, 1866, where there is an article on "Palæontology," with an account of Owen's lecture at the Government School of Mines.) [Add. to 3rd ed.]

[70] That the lowest place should be given to the rodents, seems however to proceed from *à priori* rather than from *à posteriori* considerations: that is to say, from the circumstance, that their brain has extremely faint or small convolutions; so that too much weight may have been given to this point. In sheep and calves the convolutions are numerous and deep, yet how is it with their intelligence? The mechanical instincts of the beaver are again greatly assisted by its understanding, and even rabbits show remarkable intelligence (see Leroy's beautiful work: "Lettres Philosophiques sur l'Intelligence des Animaux," lettre 3, p. 149). Even rats give proof of quite uncommon intelligence, of which some remarkable instances may be found in the "Quarterly Review," No. 201, Jan.-March, 1857, in a special article entitled "Rats."

[71] The most intelligent birds are also birds of prey, wherefore many of them, especially falcons, are highly susceptible of training. [Add. to 3rd ed.]

[72] That the negroes should have become the special victims of the slave-trade, is evidently a consequence of the inferiority of their intelligence compared with that of other human races; though this by no means justifies the fact. [Add. to 3rd ed.]

[73] As is likewise his capacity for escaping from his pursuers; for in this respect all the four-footed mammalia surpass him. [Add. to 3rd ed.]

[74] [See Third Book of the W. a. W. u. V.; later also, in my "Parerga," vol. ii. §§ 50-57 and § 206. (§§ 51-58, and § 210 of the 2nd edition.)]

[75] "Principes de Philosophie Zoologique," 1830.

[76] "Parerga," vol. ii. § 91; § 93 of the 2nd edition.

[77] See Aristotle, "De Partibus Animalium," iii. c. 2 *sub finem*: πῶς δὲ τῆς αναγκαίας φύσεως κ. τ. λ.

[78] The appearance of every animal therefore presents a totality, a unity, a perfection and a rigidly carried out harmony in all its parts which is so entirely based upon a single fundamental thought, that even the strangest animal shape seems to the attentive observer as if it were the only right, nay, only possible form of existence, and as if there could be no other than just this very one. The expression "natural" used to denote that a thing is a matter of course, and that it cannot be otherwise, is in its deepest foundation based upon this. Göthe himself was struck by this unity when contemplating whelks and crabs at Venice, and it caused him to exclaim: "How delightful, how glorious is a living thing! how well adapted for its condition; how true, how real!" ("Life," vol. iv. p. 223). No artist therefore, who has not made it his business to study such forms for years and to penetrate into their meaning and comprehension, can rightly imitate them. Without this study his work will seem as if it were pasted together: the parts no doubt will be there, but the bond which unites them and gives them cohesion, the spirit, the idea, which is the objectivity of the primary act of the will presenting itself as this or that particular species, will be wanting. [Add. to 3rd ed.]

[79] It is a great truth which Bruno expresses ("De Immenso et Innumerabili," 8, 10): "*Ars tractat materiam alienam: natura materiam propriam. Ars circa materiam est; natura interior materiæ.*" He treats this subject much more fully, "Della Causa," Dial. 3, p. 252 *et seqq.* Page 255 he declares the *forma substantialis* to be the form of every product of Nature, which is the same as the *soul*. [Add. to 3rd ed.]

[80] Thus the saying of the Schoolmen is verified: "*Materia appetit formam.*" See "Die Welt a. W. u. V." 3rd edition, vol. ii. p. 352. [Add. to 3rd ed.]

[81] Compare "Die Welt a. W. u. V." 3rd edition, vol. II. p. 375. [Add. to 3rd ed.]

[88] Treviranus, "Die Erscheinungen und Gesetze des Organischen Lebens" (Phenomena and Laws of Organic Life), vol. i. p. 173.

[89] Brandis, "On Life and Polarity," 1836, p. 88, says: "The roots of rock-plants seek nourishing mould in the most delicate crevices of rocks. These roots cling to a nourishing bone in dense clusters. I saw a root whose growth was intercepted by the sole of an old shoe: it divided itself into as many fibres as the shoe-sole had holes — those by which it had been stitched together — but as soon as these fibres had overcome the obstruction and grown through the holes, they united again to a common stem." And p. 87: "If Sprengel's observations are confirmed, even mediate relations are perceived (by plants) in order to obtain this end (fructification): that is to say, the anthers of the *nigella* bend down in order to put the pollen on the bees' backs, and the pistils bend in like manner to receive it from the bees." [Add. to 3rd ed.]

[90] In this connection I may mention an analysis of an entirely different kind, given by the French Academician Babinet in an article in which he treats of the seasons on the planets. It is contained in the No. of the 15th January, 1856, of the "Revue des Deux Mondes," and I will give the chief substance of it here in translation. The object of it is to refer to its direct cause the well-known fact, that cereals only thrive in temperate climates. "If grain did not necessarily perish in winter, if it were perennial, it would not bear ears, and there would be no harvest. In the hotter portions of Africa, Asia and America, where no winter kills the grain, these plants grow like grass with us: they multiply by means of shoots, remain always green, and neither form ears nor run to seed. In cold climates, on the contrary, the organism of these plants seems by some inconceivable miracle to feel, as it were by anticipation, the necessity of passing through the seed-phase in order to escape dying off in the winter season" (*L'organisme de la plante*, par un inconcevable miracle, *semble préssentir la nécessité de passer par l'état de graine, pour ne pas périr complètement pendant la saison rigoureuse*). In a similar way, districts which have a "droughty season," — that is to say a season in which all plants are parched up with drought— "tropical countries, for instance Jamaica, produce grain; because there

the plant, moved by the same organic presentiment (*par le même* pressentiment organique), in order to multiply, hastens to bear seed at the approach of the season in which it would have to dry up.” In the fact which this author describes as an inconceivable miracle, we recognise a manifestation of the plant’s will in increased potency, since here it appears as the will of the species, and makes preparations for the future in a similar way to animal instinct, without being guided by knowledge of that future in doing so. Here we see plants in warmer climates dispensing with a complicated process to which a cold climate alone had obliged them. In similar instances animals do precisely the same thing, especially bees. Leroy in his admirable work “Lettres Philosophiques sur l’Intelligence des Animaux” (3rd letter, p. 231) relates, that some bees which had been taken to South America continued at first to gather honey as usual and to build their cells just as when they were at home; but that when they gradually became aware that plants blossom there all the year round, they left off working. The animal world supplies a fact analogous to the above mentioned change in the mode of multiplying in cereals. This is the abnormal mode of propagation for which the *aphides* have long been noted. The female *aphide*, as is well known, propagates for 10-12 generations without any pairing with the male, and by a variety of the ovoviviparous process. This goes on all summer; but in autumn the males appear, impregnation takes place, and eggs are laid as winter quarters for the whole species, since it is only in this shape that it is able to outlive the winter. (Add. to 3rd ed.)

[116] Liebig, "Die Chemie in ihrer Anwendung auf Agrikultur," p. 394.

[117] *Ibid.* "Die Chemie in Anwendung auf Physiologie."

[118] French chemists likewise say: "*Il est évident que les métaux ne sont pas tous également* avides *d'oxygène*." ... "*La difficulté de la réduction devait correspondre nécessairement à une* avidité *fort grande du métal pour l'oxygène*." — (See Paul de Rémusat, "La Chimie à l'Exposition." "L'Aluminium," "Revue des Deux Mondes," 1855, p. 649).

Vaninus ("De Amirandis Naturæ Arcanis," p. 170) had said: "*Argentum vivum etiam in aqua conglobatur, quemadmodum et in plumbi scobe etiam: at a scobe non refugit* (this is directed against an opinion expressed by Cardanus) *imo ex ea quantum potest colligit: quod nequit (scil. colligere), ut censeo*, invitum *relinquit*: natura enim et sua appetit, et vorat." This is evidently more than a form of words. He here quite decidedly attributes a will to quicksilver. And thus it will invariably be found that where, in physical and chemical processes, there is a reference to elementary forces of Nature and to the primary qualities of bodies which cannot be further deduced, these are always expressed by words which belong to the will and its manifestations. [Add. to 3rd ed.]

[119] I only mention *one* work which has recently appeared, the explicit object of which is to show that the magnetiser's will is the real agent: "Qu'est ce que le Magnétisme?" par E. Gromier. (Lyon, 1850.)

[120] Puységur himself says in the year 1784: "*Lorsque vous avez magnétisé le malade, votre but était de l'endormir, et vous y avez réussi par le seul acte de votre volonté; c'est de même par un autre acte de volonté que vous le réveillez.*" (Puységur, "Magnét. Anim." 2me édit. 1820, "Catéchisme Magnétique," p. 150-171.) [Add. to 3rd ed.]

[122] See “Wahrheit aus Jean Paul’s Leben,” vol. viii. p. 120.

[123] I had the good fortune in the year 1854 myself to witness some extraordinary feats of this kind, performed here by Signor Regazzoni from Bergamo, in which the immediate, *i.e.* magical, power of his will over other persons was unmistakeable, and of which no one, excepting perhaps those to whom Nature has denied all capacity for apprehending pathological conditions, could doubt the genuineness. There are nevertheless such persons: they ought to become lawyers, clergymen, merchants or soldiers, but in heaven’s name not doctors; for the result would be homicidal, diagnosis being the principal thing in medicine. — Regazzoni was able at will to throw the somnambulist who was under his influence into a state of complete catalepsy, nay, he could make her fall down backwards, when he stood behind her and she was walking before him, by his mere will, without any gestures. He could paralyze her, give her *tetanos*, with the dilated pupils, the complete insensibility, and in short, all the unmistakeable symptoms of complete catalepsy. He made one of the lady spectators first play the piano; then standing fifteen paces behind her, he so completely paralyzed her by his will and gestures, that she was unable to continue playing. He next placed her against a column and charmed her to the spot, so that she was unable to move in spite of the strongest efforts. — *According to my own observation*, nearly all his feats are to be explained by his *isolating the brain from the spinal marrow*, either completely, in which case the sensible and motor nerves become paralyzed, and total catalepsy ensues; or partially, by the paralysis only affecting the *motor* nerves while sensibility remains — in other words, the head keeps its consciousness, while the body is apparently lifeless. This is precisely the effect of strychnine: it paralyzes the motor nerves only, even to complete *tetanos*, which induces death by *asphyxia*; but it leaves the sensible nerves, and with them consciousness, intact. Regazzoni does this same thing by the magic influence of his will. The moment at which this isolation takes place is distinctly visible in a peculiar trembling of the patient. I recommend a small French publication entitled “Antoine Regazzoni de Bergame à Francfort sur Mein,” by L. A. V. Dubourg (Frankfurt, Nov. 1854, 31 pages in 8vo.) on Regazzoni’s feats and the unmistakeably genuine character they bear for everyone who is not entirely devoid of all sense for organic Nature.

In the “Journal du Magnétisme,” edit. Dupotet, of the 15th August, 1856, in criticizing a treatise: “De la Catalepsie, mémoire couronné,” 1856, in 4to, the reviewer, Morin, says: “La plupart des caractères qui distinguent la catalepsie, peuvent être obtenus artificiellement et sans danger sur les sujets magnétiques, et c’est même là une des expériences les plus ordinaires des séances magnétiques.” [Add. to 3rd ed.]

[132] In the “Times” of June the 12th, 1855, we find, p. 10, the following: —

“A Horse-charmer.

“On the voyage to England the ship ‘Simla’ experienced some heavy weather in the Bay of Biscay, in which the horses suffered severely, and some, including a charger of General Scarlett, became unmanageable. A valuable mare was so very bad, that a pistol was got ready to shoot her and to end her misery; when a Russian officer recommended a Cossak prisoner to be sent for, as he was a ‘juggler’ and could, by charms, cure any malady in a horse. He was sent for, and immediately said he could cure it at once. He was closely watched, but the only thing they could observe him do was to take his sash off and tie a knot in it three several times. However the mare, in a few minutes, got on her feet and began to eat heartily, and rapidly recovered.” [Add. to 3rd ed.]

[155] Krusenstern's words are: "A universal belief in witchcraft, which is held to be very important by all islanders, seems to me to be connected with their religion; for they assert that the priests alone possess magic power, although some of the common people also, it is said, profess to have the secret, probably in order to make themselves feared, and to exact presents. This sorcery, which they call *Kaha*, consists in inflicting a lingering death upon those to whom they bear a grudge, twenty days being however fixed as the term for this. They go to work as follows. Whoever wishes to practise revenge by means of sorcery, seeks to procure either saliva or urine or excrements of his enemy in some way or other. These he mixes with a powder, lays the compound in a bag which is woven in a special manner, and buries it. The most important secret is in the art of weaving the bag in the right way and of preparing the powder. As soon as it is buried, the effects show themselves in the person who is the object of this witchcraft. He sickens, becomes daily weaker, loses at last all his strength,

and in twenty days is sure to die. If, on the other hand, he attempts to divert his enemy's revenge from himself by offering up a pig, or making some other valuable present in order to save his life, he may yet be saved, even on the nineteenth day, and no sooner is the bag unburied, than the attacks of illness cease. He recovers gradually, and after a few days is quite restored to health."— "Reise um die Welt." Ed. in 12mo, 1812, Part i., p. 249 *et seq.* [Add. to 3rd ed.]

[156] Kieser, "Archiv für thierischen Magnetismus," vol. ix. s. i. in the note, pp. 128-132.

[157] They scent something of the

"Nos habitat, non tartara sed nec sidera cœli:

Spiritus in nobis qui viget, illa facit."

(Not in the heavens it lives, nor yet in hell;

The spirit that does it all, doth in us dwell.)

Compare Johann Beaumont, "Historisch-Physiologisch-und Theologischer Tractat von Geistern, Erscheinungen, Hexereyen und andern Zauber-Händeln, Halle im Magdeburgischen, 1721," p. 281. [Add. to 3rd ed.]

[158] Compare Parerga, vol. i. p. 257 (2nd ed. vol. i. p. 286).

[159] On the 4th of August, 1856, the Roman Inquisition issued a circular to all the bishops, in which it called upon them in the name of the Church to use their utmost influence against the practice of Animal Magnetism. The reasons for this are given with striking want of lucidity and great vagueness, and even here and there are not unmixed with falsehood; and it is easy to see that the Church is reluctant to own the real reason. This circular is published in the "Turin Journal" of December, 1856, and again in the French "Univers," and reprinted from this in the "Journal des Débats" of January 3rd, 1857. [Add. to 3rd ed.]

[160] According to a Chinese official Report on the census, printed in Pekin, and found by the English in the Chinese Governor's palace on entering Canton, China had 396 millions of inhabitants in 1852, and allowing for a constant increase, may now have 400 millions. ("Moniteur de la Flotte," end of May, 1857.)

The Reports of the Russian Clerical Mission in Pekin give the returns of 1842 as 414,687,000.

According to the tables published by the Russian Embassy at Pekin, the population, in 1849, amounted to 415 millions. ("Post-Zeitung," 1858.) [Add. to 3rd ed.]

[161] For the benefit of those who wish to acquire a fuller knowledge of Buddhism, I here note down those works belonging to its literature, and written in European languages, which I can really recommend, for I possess them and know them well; the omission of a few others, for instance of Hodgson's and A. Rémusat's books, is intentional.

1. "Dsanglun, or the Sage and the Fool," in Tibetan and German, by I. J. Schmidt, Petersburg, 1843, 2 vols. in 4to, contains in the preface to vol. i. (*i.e.* the Tibetan volume), from pp. xxxi to xxxviii, a very brief, but excellent, sketch of the whole doctrine, admirably calculated for a first introduction to the knowledge of it: the whole book even, as a part of the Kandshur (canonical books), may be recommended. — 2. In the Memoranda of the Academy of St. Petersburg are to be found several lectures by the same excellent author (I. J. Schmidt), which were delivered in German in that Academy in 1829-1832. As they are of very great value for the knowledge of this religion, it is to be hoped that they will be collected and published all together in Germany. — 3. By the same writer: "Forschungen über die Tibeter und Mongolen." Petersb. 1829, in 4to. (Investigations concerning the Tibetans and Mongols). — 4. By the same writer: "Über die Verwandtschaft der gnostisch-theosophischen Lehren mit dem Buddhaismus," 1828. (On the relation between the Gnostic-Theosophic Doctrines and Buddhism.) — 5. By the same: "Geschichte der Ost-Mongolen," Petersb. 1829, in 4to. (History of the Eastern Mongols.) [This is very instructive, especially the explanations and appendix, which give long extracts from writings on Religion, in which many passages clearly show the deep meaning and breathe the genuine spirit of Buddhism. — Add. to 3rd ed.] — 6. Two treatises by Schiefner in German, in the "Mélanges Asiatiques tirés du Bulletin Historico-Philol. de l'Acad. d. St. Pétersburg," Tome 1, 1851. — 7. "Samuel Turner's journey to the Court of the Teshoo-Lama" (at the end), 1801. — 8. Bochinger, "La Vie ascétique chez les Indous et les Bouddhistes," Strasbourg, 1831. — 9. In the 7th vol. of the "Journal Asiatique," 1825, an extremely beautiful biography of Buddha by Deshauterayes. — 10. Bournouf, "Introd, à l'Hist, d. Bouddhisme," vol. i. in 4to, 1844. — 11. "Rgya Tsher Rolpa," traduit du Tibétain, par Foucaux, 1848, in 4to. This is the "Lalita Vistara," *i.e.* life of Buddha, the gospel of the Buddhists. — 12. "Foe Koue Ki, relation des royaumes Bouddhiques," traduit du Chinois par Abel Rémusat, 1836, in 4to. — 13. "Description du Tubet," traduit du Chinois en Russe par Bitchourin, et du Russe en Français par Klaproth, 1831. — 14. Klaproth, "Fragments Bouddhiques," printed separately from the "Nouveau Journal Asiatique," Mars, 1831. — 15. Spiegel, "De officiis sacerdotum Buddhicorum," Palice et Latine, 1841. — 16. The same author's "Anecdota Palica," 1845. — [17. "Dhammapadam," palice edidet et latine vertit Fausböll, Hovniæ, 1855. — Add. to 3rd ed.] — 18. Asiatic Researches, vol. vi. Buchanan, "On the Religion of the Burmas," and vol. xx. (Calcutta, 1839), Part 2, contains three important articles by

Csoma Körösi, including Analyses of the Books of the Kandshur. — 19. Sangermano, “The Burmese Empire,” Rome, 1833. — 20. Turnour, “The Mahawanzo,” Ceylon, 1836. — 21. Upham, “The Mahavansi, Raja Ratnacari et Rajavali,” 3 vols. 1833. — 22. *ejusd.* “Doctrine of Buddhism,” 1839, fol. — 23. Spence Hardy, “Eastern Monachism,” 1850. — 24. *ejusd.* “Manual of Buddhism,” 1853. The two last books, written after a twenty years’ stay in Ceylon and from oral information supplied by the priests there, have given me a deeper insight into the essence of the Buddhist dogma than any other work. They deserve to be translated into German, but without abridgement, for otherwise the best part might be left out. — [25. C. F. Köppen, “Die Religion des Buddha,” 1857, a complete compendium of Buddhism, compiled not only with great erudition and serious industry but also with intelligence and insight from all the other works I have mentioned above and from many more besides, which contains all that is essential on the subject. — 26. “The Life of Buddha,” from the Chinese of Palladji, in the “Archiv für wissenschaftliche Kunde von Russland,” edited by Erman, vol. xv. Heft 1, 1856. — Add. to 3rd ed.]

[162] This is equivalent to imputing to the Chinese the thought, that all princes on earth are tributary to their Emperor. [Add. to 3rd ed.]

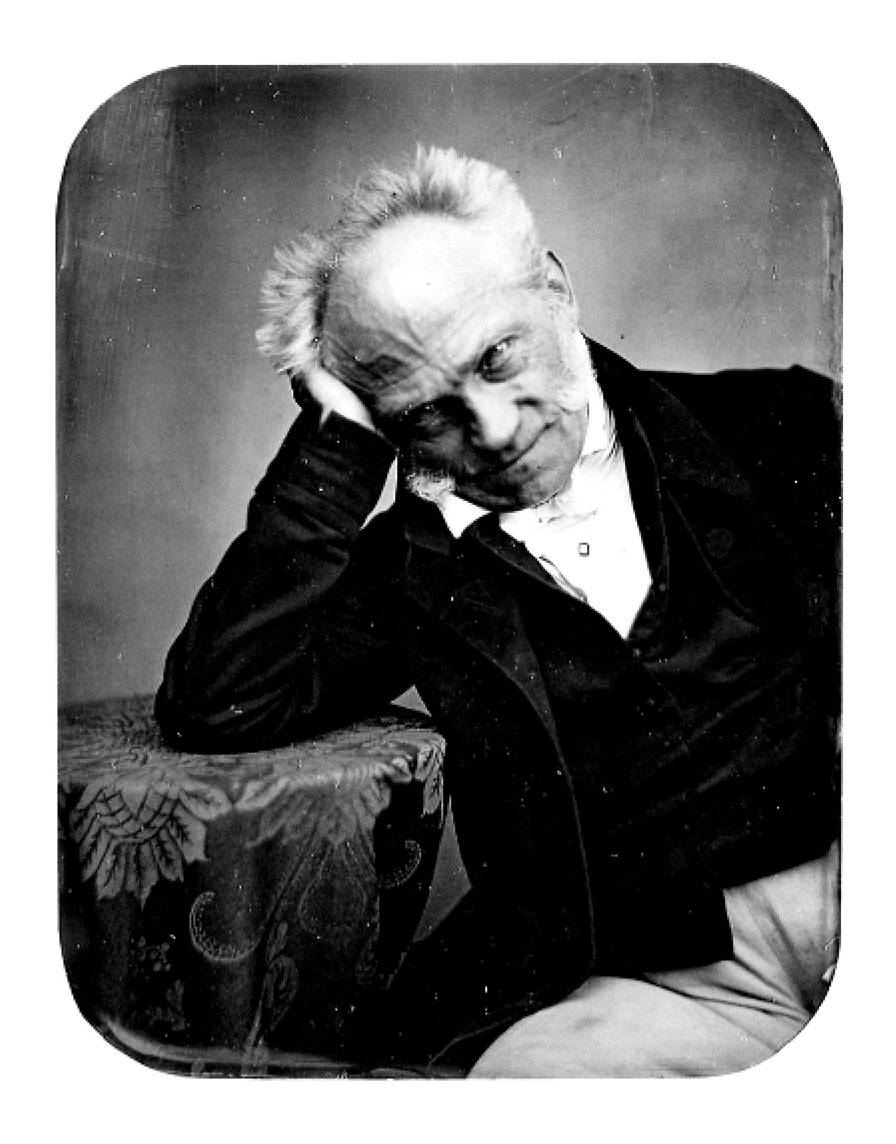
ON THE BASIS OF MORALITY

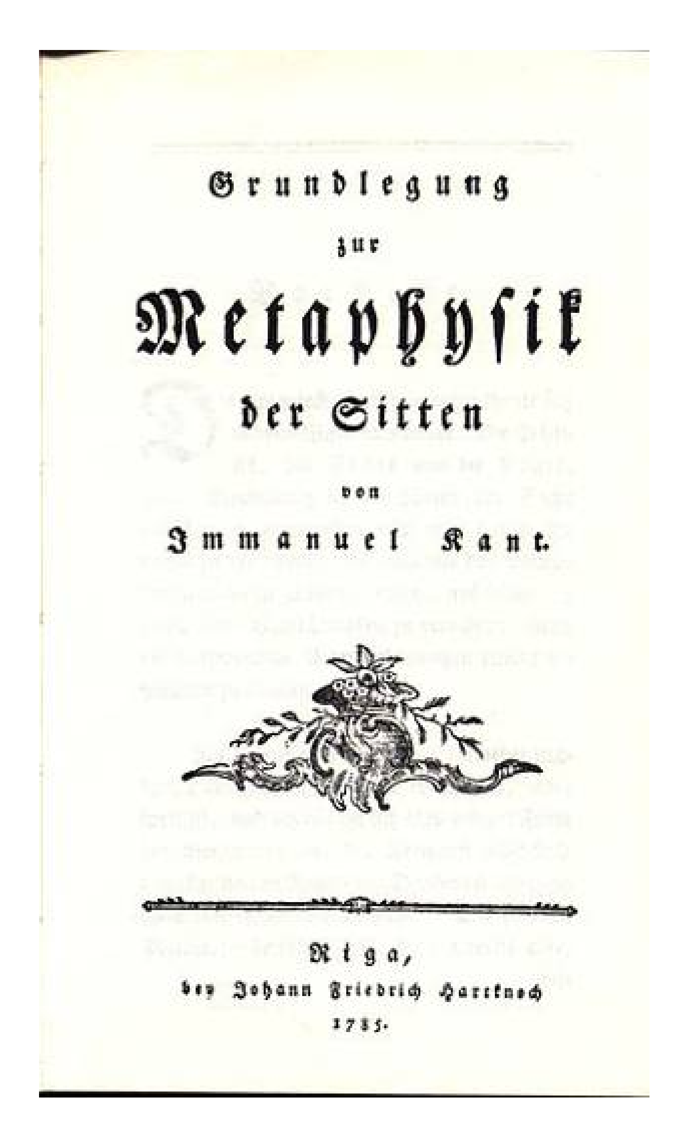
Translated by Arthur Broderick Bullock



This major work on ethics argues that morality stems from compassion. Schopenhauer begins with a criticism of Kant's *Groundwork of the Metaphysic of Morals*, which he considers to be the clearest explanation of Kantian ethics.

The treatise was written as a response to a question posed by the Royal Danish Society of Scientific Studies in 1837 for an essay contest. The question was, "Are the source and foundation of morals to be looked for in an idea of morality lying immediately in consciousness (or conscience) and in the analysis of other fundamental moral concepts springing from that idea, or are they to be looked for in a different ground of knowledge?" Schopenhauer submitted the only entry to the contest in July 1839, though he was not awarded the prize. On January 17, 1840, the society published a response to the essay, in which they refused to present him with the prize, claiming that he had misunderstood the question. Schopenhauer on the preface of the essay's publication went on to analyse the original question and preamble, later stating "I have proved incontrovertibly that the Royal Danish Society really did ask what it denies having asked; and on the contrary that it did not ask what it claims to have asked, and indeed could not even have asked it."

The Society's Judicium also read "Nor should it go unmentioned that several distinguished philosophers of recent times are mentioned in such an indecent fashion as to provoke just and grave offence". In response Schopenhauer, outraged, wrote: "These 'distinguished philosophers' are in fact — Fichte and Hegel!" This was followed by a series of invectives and quoting Hegel, attempting to show with three different examples that Hegel "lacked even common human understanding".



On the Basis of Morality is divided into four sections. The first section is an introduction in which Schopenhauer provides his account of the question posed by the Royal Danish Society and his interpretation of the history of western ethics. In the second section, Schopenhauer embarks on a criticism of Kantian ethics, which he views as the orthodoxy in ethics. The third

section of the work is Schopenhauer's positive construction of his own ethical theory. The final section of the work provides a brief description of the metaphysical foundations of ethics.

TRANSLATOR'S PREFACE.

This translation was undertaken in the belief that there are many English-speaking people who feel more than a merely superficial interest in ethical research, but who may not read German with sufficient ease to make them care to take up the original. The present Essay is one of the most important contributions to Ethics since the time of Kant, and, as such, is indispensable to a thorough knowledge of the subject. Moreover, from whatever point of view it be regarded, — whether the reader find, when he closes the book, that his conviction harmonises with the conclusion reached, or not; it would be difficult to find any treatise on Moral Science more calculated to stimulate thought, and lift it out of infantile imitation of some prescribed pattern. The believer in the Kantian, or any other, basis of Ethics, could hardly measure the strength or the weakness of his own position more surely than by comparing it with the Schopenhauerian; while he who is yet in search of a foundation will find much in the following pages to claim his attention.

Those acquainted with the luminous imagery, the subtle irony, the brusque and penetrating vigour of the German, will doubtless admit that it is no easy task to reduce Schopenhauer to adequate English prose; and if this has been attempted by the present writer, no one can be more conscious than he of the manifold shortcomings discoverable. But such as it is, the work is heartily offered to all who still follow the true student's rule, "Gladig wolde he lerne und gladig teche," with the single hope that it may help, however slightly, to widen their knowledge, and ripen their judgment.

My friend, R. E. Candy, Esq., I.C.S., has kindly given me information concerning several Indian names.

ROME: *June*, 1902.

TRANSLATOR'S INTRODUCTION.

Ὂν δὲ θεοὶ τιμῶσιν, ὁ καὶ μωμεύμενος αἰνεῖ.
— Theognis: 169.

In 1837 the Danish Royal Society of Sciences propounded, as subject for a prize competition, the question with which this treatise opens; and Schopenhauer, who was glad to seize the opportunity of becoming better known, prepared, and sent to Copenhagen, the earliest form of "The Basis of Morality." In January, 1840, the work was pronounced unsuccessful, though there was no other candidate. In September of the same year it was published by the author, with only a few unimportant additions, but preceded by a long introduction, which, cast in the form of an exceedingly caustic philippic, is, in its way, a masterpiece. In 1860, (only a month before Schopenhauer's death,) the second edition was printed with many enlargements and insertions, the short preface, dated August being one of the last things he wrote.[1]

The reason why the prize was withheld is not far to seek, and need not detain us. At that time the philosophical atmosphere was saturated with Hegel, and, to a certain extent, with Fichte; hence it is easy to imagine with what ruffled, not to say, scandalised feelings the Academy must have risen from its perusal of the work. Moreover, putting Hegel and Fichte out of the question, the position advanced was in 1840 so new, indeed so paradoxical (as Schopenhauer himself admits); there is at times such an aggressiveness in the style; the whole essay is so much more calculated to startle than to conciliate; that we cannot feel much surprise at the official decision.

In the Judgment published by the Society three reasons are given for its unfavourable attitude. The second is declared to be not only dissatisfaction with the mode of discussion (*ipsa disserendi forma*), but also inability to see that Schopenhauer proves his case. As the third is alleged the "unseemly" language employed in connection with certain "*summi philosophi*" (Hegel and Fichte). These two objections are of course in themselves perfectly legitimate, and how far the Academy was right or wrong may be left for the reader to determine.

But the first reason stated is of a different kind, and affords as neat an instance of self-stultification proceeding *ex cathedra* as can well be found. It is true that the question is worded vaguely enough, but if it means anything, it asks where the "*philosophiae moralis fons et fundamentum*" — the foundation of moral science — is to be sought for, *i.e.*, where it is to be found. Turning to the Judgment we read: "He" (Schopenhauer) "has omitted to deal with the essential part of the question, apparently thinking that he was required to establish some fundamental principle of Ethics": which he was required to do, unless the Society's Latin is borrowed from *Νεφαλοκοκκυγία.* And then it goes on to declare that he treated as secondary, indeed as an *opus supererogationis,* the very thing which the Academy intended should occupy the first place, namely, the connection between Metaphysics and Ethics.[2] But the "*metaphysicae et ethicae nexus*," so far from being formulated in the question as the chief point to be considered, is not even mentioned! The Society thus denies having asked what it actually did ask, while the discussion, which it asserts was specially indicated, is not suggested by a single word. Its embarrassment is sufficiently shown by this unworthy shifting, to enlarge upon which would here be out of place.[3]

It is not intended to offer any criticism either on Schopenhauer's main position in this essay, or on the various side-issues involved. The reader is supposed to be accurately acquainted with the fundamentals of his philosophy, as contained in *Die Welt als Wille und Vorstellung*, and is invited to be the critic himself. But perhaps a few remarks on the structure and general trend of the work may not be amiss.

After preliminary considerations, partly to show the difficulty of the subject, partly to clear the ground (Part I.), the treatise opens with a searching critique of Kant's Ethical Basis, of the Leading Principle of his system, and of its derived forms. (Part II., Chapters I.-VI.)[4] Schopenhauer's conclusion is that the Categorical Imperative is a very cleverly woven web, yet in reality nothing but the old theological basis in disguise, the latter being the indispensable, if invisible, clothes' peg for the former; and that Kant's *tour de main* of deducing his Moral Theology from Ethics is like inverting a pyramid. The theory of Conscience is next discussed (Chapter VII.). The half-supernatural element which Kant introduced under the highly dramatic form of a court of justice holding secret session in the

breast, is examined, and eliminated; and Conscience is defined as the knowledge that we have of ourselves through our acts.

But if, so far, the result obtained is distinctly unfavourable to Kant, Schopenhauer is glad to agree with him on one point, namely, the theory of Freedom, to a brief notice of which he now passes (Chapter VIII.). He points out that the solution of this question is found in the doctrine of the co-existence of Liberty and Necessity: according to which the basis of our nature, the so-called Intelligible Character, that lies outside the forms attaching to phaenomena, namely, Time, Space, and Causality, is transcendentally free; while the Empirical Character, together with the whole person, being, as a phaenomenon, the transient objectivation of the Intelligible Character, under the laws of the *principium individuationis*, is strictly determined.[5] Part II. closes with a sufficiently amusing examination of Fichte (Chapter IX.). His proper function is shown to be that of a magnifying glass for Kant. By means of this powerful human lens we can see the monstrous shapes into which the Kantian pet creations are capable of developing. Thus we find the Categorical Imperative become a Despotic Imperative, the "Absolute Ought" grown into a fathomless inscrutable *Εἱμαρμένη*, etc.

With Part III. we reach the positive part of the work. Schopenhauer begins (Chapter I.) by emphasising the necessity of finding a basis for Ethics that appeals, not to the intellect, but to the intuitive perception. Such (he says) can never be any artificial formula, which surely crumbles to powder beneath the rough touch of real life; rather must it be something springing out of the heart of things, and therefore lying at the root of man's nature. But is there, he asks (Chapter II.), after all, such a thing as natural morality? Is anything good ever done absolutely without an egoistic motive? The conclusion arrived at is that, although much may be, and has been, at all times, said in favour of the Sceptical View, and although this view is in fact true as regards the greater number of apparently unselfish acts, yet there can be no doubt that truly moral conduct does occur, that deeds of justice and loving-kindness are occasionally performed without the smallest hope of reward, or fear of punishment involved in their omission. The last paragraph of chis chapter is important because it puts in the clearest light what, according to Schopenhauer, is the end of Ethics. Its aim, he says, is not to treat of that which people ought to do (for "ought" has no place except in theological Morals, whether explicit, or implicit); but "to

point out all the varied moral lines of human conduct; to explain them; and to trace them to their ultimate source.” This definition, which assigns no educative function to Ethics, strictly agrees with the doctrine of the unchangeableness of character. (*V*. Chapter IX. of this Part.)

Our philosopher then proceeds to show (Chapter III.) that there are two fundamental “antimoral” incentives in man’s nature: Egoism and Malice. Be it, however, here remarked that a still simpler classification would reduce these two to one. Malice may well be regarded as nothing but Egoism carried to its extreme, developed to gigantic proportions. It is a distinct source of gratification to certain natures to witness the suffering of another; because a diminution of the latter’s capacity for action, whether effected by itself, or not, is regarded by an ego of this kind as an increase of its own power to do as it likes, — as an enhancement of its own glorification.

In Chapter IV. the ultimate test of truly moral conduct is explained to be the absence of all egoistic motivation; and in Chapters V.-VII., by a process of careful reasoning, every human act is traced to one of three original springs, namely, (1) Egoism, (2) Malice, and (3) Compassion; or to a combination of (1) and (3), or (1) and (2).[6] Of these the third is shown to be the only counter-motive to the first and second, and in fact the sole source of the two cardinal virtues, justice and loving-kindness, which are explained as the manifestation of Compassion in a lower, and a higher, degree, respectively. In the course of the demonstration the question as to how far a lie is legitimate comes incidentally under discussion; as also the theory of Duty; duties being defined as “actions, the simple omission of which constitutes a wrong.” (Cf. Part II., Chapter III.)

The position now reached, namely, that Compassion is the one and only fount of true morality, because it is the sole non-egoistic source of action, is (says Schopenhauer) a strange paradox; hence the testimony of experience and of universal human sentiment is appealed to, in confirmation of it, under nine different considerations (Chapter VIII.). They are as follows: —

(1) An imaginary case.

(2) Cruelty, which means the maximum deficiency in Compassion, is the mark of the deepest moral depravity. Therefore the real moral incentive must be Compassion.

(3) Compassion is the only thoroughly effective spring of moral conduct.

(4) Limitless Compassion for all living things is the surest and most certain token of a really good man.

(5) The evidence of separate matters of detail.

(6) Compassion is more easily discerned in its higher power; it is more obviously the root of loving-kindness than of justice.

(7) Compassion does not stop short with men; it includes all living beings.

(8) Considered simply from the empirical point of view, Compassion is the best possible antidote to Egoism, no less than the most soothing balsam for the world's inevitable suffering.

(9) Rousseau's testimony is quoted, as well as passages from the Paṅćatantra, Pausanias, Lucian, Stobaeus, and Lessing; and reference is made to Chinese Ethics and Hindu customs.

Part III. closes (Chapter IX.) with an inquiry into the Ethical Difference of Character. The theory that this difference is innate and immutable is supported by numerous extracts from various writers of all periods, and illustrated in many ways. But all the evidence accumulated hardly amounts to more than so many hints and indications, and the matter (says Schopenhauer) was only satisfactorily explained by Kant's doctrine of the Intelligible and Empirical Character. (Cf. Part II., Chapter VIII.) According to this, the ethical difference between man and man is an original and ultimate datum, caused by the transcendentally free act of the Intelligible Character, that is, the Will, as Thing in itself, outside phaenomena; the Empirical Character being, so to say, the reflection of the Intelligible, mirrored through the functions of our perceptive faculty, namely, Time, Space, and Causality. Hence the former, while manifested in plurality and difference of acts, yet necessarily always wears the same unchangeable features, inasmuch as it is but the appearance-form of the unity behind. If the reader asks why "the essential constitution of the Thing in itself underlying the phaenomenon" is so enormously different in different individuals, it can only be said that our intellect, conditioned, as it is, by the laws of Causality, Space, and Time, has no power to deal with noumena, its range being limited to phaenomena; and that therefore this question is one of those which have no conceivable answer. (Cf. *Die Welt als Wille und Vorstellung*, vol. ii., chap. 50., Epiphilosophie.)[7]

The discussion now terminated points to the conclusion that nine-tenths, or perhaps nineteen-twentieths, of what we do is, more or less, due to Egoism, conscious or unconscious; while acts of real morality, that is, of unselfish justice and pure loving-kindness (admitting that they occur) are to be attributed to Compassion, that is, the sense of suffering with another. Nor is the principle of Altruism new. It is as old as man himself. All the rare and sensitive natures in the world have given utterance to it, each in his own way. Like a golden thread it runs from the earliest Indian literature to George Eliot, to Tolstoï; and every day, for unnumbered ages, "from youth to eld, from sire to son," in lowly dwellings and in princes' palaces, it has been unawares translated into action.

And if we may forecast the future from the past, it would appear that in all the stormy seas yet to be traversed by the human race, before its little day is spent, Compassion will ever be the surest guide to better things; and that the light of knowledge illuminating the path, whereby the world may become relatively happier, will always vary directly as man's susceptibility to its promptings: for "Durch Mitleid wissend" is not truer of Parsifal than of all other saviours.

In the fourth Part of the treatise Schopenhauer attempts the metaphysical explanation of Compassion, which for those, who still think that Metaphysics is something more than a pseudo-science of the past — like Alchemy or Astrology — will have special interest.

It should be observed (as is pointed out in our author's Preface to the first edition) that the line of thought followed does not belong to any particular metaphysical school, but to many; being in fact a principle at the root of the oldest systems in the world, and traceable in one form or another down to Kant. As in the dawn of history it was our own Aryan forefathers, who divined with subtle intuition the ideality of Time and Space; so in the fulness of the ages it was reserved for another Aryan of Scotch descent to formulate the same in exact language. Now, by the vast majority of men the ideality of the *principium individuationis* is undoubtedly either not consciously realised at all, or else but dimly perceived under the form of allegories and mythologies. Yet, if this theory be true, if individuation be only a phaenomenon depending on the subjectivity of Time and Space, then Compassion, and its external expression, the *ἀγάπη* that is greater than Faith and Hope, receive their final explanation. And every *εὐθανασία*; every word

that vibrates in harmony with the inspired rhapsody of 1 Corinthians xiii.; every act of genuine justice, or of true loving-kindness, done by man to man, as well as the uplifting emotion which stirs our hearts at the sight of such conduct: — all these things become fraught with a new and luminous significance: the secret writing is interpreted, its deepest meaning disclosed.

Moreover, the "thou shalt," and the "thou shalt not," no less of the various theologies than of the Categorical Imperative, may from this point of view be accounted for, on the ground of the identity of man, so far as he is noumenal, with the transcendental Reality behind phaenomena. The crude threats of punishment and promises of reward, the stern Moral Law, poised in mid air, — these hypotheses, and all their varieties (whose function is in reality nothing else but to check Egoism), are seen to be due to the intellect's imperfect comprehension of, or rather, its vague groping after, the transcendental unity of life, however individualised and differentiated as a phaenomenon in Time and Space.[8] It thus becomes apparent that the position developed by Schopenhauer in the third and fourth parts of the Essay is not so much destructive, as explanatory, of the usual theories, which, if once the former be fully grasped, lose themselves in it as stars and moon in the light of day. They are at once interpreted, and shown to be no longer of importance. Similarly, all the religions of the world, "which are the Metaphysics of the people," find their *raison d'être* in the same doctrine. The theory of an external *δημιουργὸς* takes its place as the natural mode of denoting, in children's language, the internal metaphysical Entity, whose appearance-form, in terms of our consciousness, is called the Universe. The circle is completed; the discords vanish, and an ultimate harmony is reached. And so over the thrice-tangled skein of phaenominal existence a simplifying and integrating light is shed, showing that the *πᾶν* is but the reflection of the *ἕν*, under the forms of our faculty of perception, namely, Time, Space, and Causality — forms, which necessarily imply plurality and change, on which, again, in the last resort the *Welt-Schmerz* depends.

"The One remains, the many change and pass;
. . . .
Life, like a dome of many-coloured glass,
Stains the white radiance of Eternity,
Until Death tramples it to fragments."

“What an unspeakable gain,” says Richard Wagner,[9] “we should bring to those who are terrified by the threats of the Church, and, on the other hand, to those who are reduced to despair by our physicists, if we could quicken the noble edifice of ‘Love, Faith, and Hope,’ with a clear consciousness of the ideality of the world, conditioned by the laws of Space and Time, which form the sole basis of our perceptive capacity! In that case all anxious inquiries as to a ‘Where’ and ‘When’ of the ‘other world’ would be understood to be only answerable by a blissful smile. For, if there is a solution to these questions, which seem of such boundless importance, our philosopher has given it with incomparable precision and beauty in the following sentence, which, to a certain extent, is only a corollary to the definition of the ideality of Time and Space: ‘Peace, Rest, and Bliss dwell only there where there is no where, and no when.’” (*V.* Schopenhauer: *Parerga and Paralipomena,* vol. ii., chap. 3, § 30 bis.)

ENDNOTES.

[1] He died September 21st.

[2] It should be noticed that this “essential part of the question,” a few lines before, is said to have been passed over altogether (*omisso enim eo, quod potissimum postulabatur*).

[3] Any one who cares to see how this Judgment, the Danish Royal Society of Sciences, Hegel, Fichte, and “Professors of Philosophy” in general, are all pulverised together under our sage’s withering wrath and trenchant irony, should read his Introduction to each Edition.

[4] Incidentally (Chapter III.), duties towards ourselves, properly so called, are shown to be non-existent from the Schopenhauerian standpoint. Cf. the definition of Duty in Part III., Chapter VI.

[5] Schopenhauer treated this subject exhaustively in his Essay on “The Freedom of the Will,” which, written immediately before, and more fortunate than, the present treatise, was awarded the prize by the Royal Norwegian Society of Sciences in January, 1839.

[6] If, as above suggested, Malice be taken as a form of Egoism, we may simplify as follows: —

Egoism.	Compassion.
(*a*) Lower power: seen in	(*a*) Lower power: seen in
selfishness, covetousness, etc.	justice.
(*b*) Higher power: seen in	(*d*) Higher power: seen in
malice, cruelty, etc.	loving-kindness.

Egoism (not in its higher power) may be simultaneously operative with Compassion in every possible proportion.

[7] *V*. Also the *Neue Paralipomena*, chap. vii.; *Zur Ethik,* § 248, where Schopenhauer calls this "the hardest of all problems." On the one hand, we have the metaphysical unity of the Will, as Thing in itself, which, as the Intelligible Character, is present, whole and undivided, in all phaenomena, in every individual; on the other hand, we find, as a fact of experience, the widest possible difference in the Empirical Character, no less of animals than of men. That is to say, "*difference*" must be predicated of the Thing in itself! It is obvious that we here touch a contradiction, which, for the rest, lies at the root of the Schopenhauerian doctrine of the Will.

[8] The reader will remember the fine poetic presentment of this view of things, which Goethe with intuitive perception gives in the Faust, Part I., where the Erdgeist says:

"*So schaff' ich am sausenden* WEBSTUHL DER ZEIT,
Und wirke DER GOTTHEIT LEBENDIGES KLEID."

[9] V. *Gesammelte Schriften und Dichtungen* von Richard Wagner. Zweite Auflage, vol. x. "Was nützt diese Erkenntnis?" p. 361: — *Welchen unsäglichen Gewinn würden wir aber den einerseits von den Drohungen der Kirche Erschreckten, andererseits den durch unsere Physiker zur Verzweiflung Gebrachten zuführen, wenn wir dein erhabenen Gebäude von "Liebe, Glaube und Hoffnung" eine deutliche Erkenntnis der, durch die unserer Wahrnehmung einzig zu Grunde liegenden Gesetze des Raumes und der Zeit bedingten, Idealität der Welt einfügen könnten, durch welche dann alle die Fragen des beängstigten Gemüthes nach einem "Wo" und "Wann" der "anderen Welt" als nur durch ein seliges Lächeln beantwortbar erkannt werden müssten? Denn, giebt es auf diese, so grenzenlos wichtig dünkenden Fragen eine Antwort, so hat sie unser Philosoph, mit unübertrefflicher Präzision und Schönheit, mit diesem, gewissermaassen nur der Definition der Idealität von Zeit und Raum beigegebenen Ausspruche ertheilt: "Frieda, Ruhe, und Glückseligkeit wohnt allein da, wo es* KEIN WO UND KEIN WANN *giebt."*

THE QUESTION

The question advanced by the Royal Society, together with the considerations leading up to it, is as follows: —

Quum primitiva,', moralitatis idea, sive de summa lege morali principalis notio, sua quadam 'propria eaque minime logica necessitate, turn in ea disciplina appareat, cui propositum est cognitionem τοῦ ἡθικοῦ *explicare, turn in vita, partim in conscientiae judicio de nostris actionibus, partim in censura morali de actionibus aliorum hominum; quumque complures, quae ab illa ider inseparables sunt, eamque tanquam originem respiciunt, notiones principales ad* τὸ ἡθικόν *spectantes, velut officii notio et imputationis, eadem necessitate eodemque ambitu vim suam exserant, — et tamen inter eos cursus viasque, quas nostrae aetatis meditatio philosophica persequitur, magni momenti esse videatur, hoc argumentum ad disputationem revocare, — cupit Societas, ut accurate haec quaestio perpendatur et pertractetur:*

Philosophiae moralis fons et fundamentum utrum in idea moralitatis, quae immediate conscientia contineatur, et ceteris notionibus fundamentalibus, quae ex illa prodeant, explicandis quaerenda sunt, an in alio cognoscendi principio?

(The original idea of morality, or the leading conception of the supreme moral law, occurs by a necessity which seems peculiar to the subject, but which is by no means a logical one, both in that science, whose object it is to set forth the knowledge of what is moral, and also in real life, where it shows itself partly in the judgment passed by conscience on our own actions, partly in our moral estimation of the actions of others; moreover, most of the chief conceptions in Ethics, springing as they do out of that idea, and inseparable from it (as, for instance, the conception of duty, and the ascription of praise or blame) assert themselves with the same necessity, and under the same conditions. In view of these facts and because it appears highly desirable, considering the trend of philosophic investigation in our time, to submit this matter to further scrutiny; the Society desires that the following question be carefully considered and discussed: —

Is the fountain and basis of Morals to be sought for in an idea of morality which lies directly in the consciousness (or conscience), and in the analysis

of the other leading ethical conceptions which arise from it? or is it to be found an some other source of knowledge?)

PART I. INTRODUCTION.

CHAPTER I.

THE PROBLEM.

"Why do philosophers differ so widely as to the first principles of Morals, but agree respecting the conclusions and duties which they deduce from those principles?"

This is the question which was set as subject for a prize essay by the Royal Society of Holland at Harlem, 1810, and solved by J. C. F. Meister; and in comparison with the task before us, the inquiry presented no extraordinary difficulty. For: —

(1) The present question of the Royal Society has to do with nothing less important than the objectively true basis of morals, and consequently of morality. It is an Academy, be it observed, which invites this inquiry; and hence, from its position, it has no practical purpose in view; it asks for no discourse inculcating the exercise of uprightness and virtue, with arguments based on evidence, of which the plausibility is dwelt on, and the sophistry evaded, as is done in popular manuals. Rather, as its aim is not practical, but only theoretical, it desires nothing but the purely philosophical, that is, the objective, undisguised, and naked exposition of the ultimate basis of all good moral conduct, independent of every positive law, of every improved assumption, and hence free from all groundwork, whether metaphysical or mythical. This, however, is a problem whose bristling difficulties are attested by the circumstance that all philosophers in every age and land have blunted their wits on it, and still more by the fact that all gods, oriental and occidental, actually derive their existence therefrom. Should therefore this opportunity serve to solve it, assuredly the Royal Society will not have expended its money amiss.

(2) Apart from this, a peculiar disadvantage will be found to attach to any theoretical examination of the basis of morals, because such an investigation is suspiciously like an attempt to undermine, and occasion the collapse of, the structure itself. The fact is, that in this matter we are apt to so closely associate practical aims with theory, that the well-meant zeal of the former is with difficulty restrained from ill-timed intervention. Nor is it within the power of every one to clearly dissociate the purely theoretical search for objective truth, purged of all interest, even of that of morality as practised, from a shameless attack on the heart's sacred convictions.

Therefore he, who here puts his hand to the plough, must, for his encouragement, ever bear in mind that from the doings and affairs of the populace, from the turmoil and bustle of the market-place, nothing is further removed than the quiet retreat and sanctuary of the Academy, where no noise of the world may enter, and where the only god raised on a pedestal is Truth, in solitary, naked sublimity.

The conclusion from these two premises is that I must be allowed complete freedom of speech, as well as the right of questioning everything; and furthermore, that if I succeed in really contributing something, however small, to this subject, then that contribution will be of no little importance.

But there are still other difficulties obstructing my path. The Royal Society asks for a short monograph setting forth the basis of Ethics entirely by itself; which means to say, independent of its connection with the general system, *i.e.*, the actual metaphysics of any philosophy. Such a demand must not only render the accomplishment of the task more difficult, but necessarily make it imperfect. Long ago Christian Wolff, in his *Philosophia Practica* (P. II., § 28) observed: "*Tenebrae in philosophia practica non dispelluntur, nisi luce metaphysica effulgente*" (Darkness in practical philosophy is only dispersed, when the light of metaphysics shines on it;) and Kant in the Preface to his *Grundlegung zur Metaphysik der Sitten* remarks: "Metaphysics must precede, and is in every case indispensable to, moral philosophy." For, just as every religion on earth, so far as it prescribes morality, does not leave the latter to rest on itself, but backs it by a body of dogmas (the chief end of which is precisely to be the prop of the moral sense); so with philosophy, the ethical basis, whatever it be, must itself attach to, and find its support in, one system of metaphysics or another, that is to say, in a presupposed explanation of the world, and of existence in general. This is so, because the ultimate and true conclusion concerning the essential nature of the Universe must necessarily be closely connected with that touching the ethical significance of human action; and because, in any case, that which is presented as the foundation of morality, if it is not to be merely an abstract formula, floating in the clouds, and out of contact with the real world, must be some fact or other discoverable either in the objective kosmos, or else in man's consciousness; but, as such, it can itself be only a phaenomenon; and consequently, like all other phaenomena, it requires a further explanation; and this explanation is supplied by Metaphysics. Philosophy indeed is such a connected whole that

it is impossible to exhaustively discuss any one part without all the others being involved. Thus Plato says quite correctly: *ψυχῆs οὖν φύσιν ἀξίως λόγου κατανοῆσαι οἴει δυνατὸν εἶναι, ἄνευ τῆς τοῦ ὅλον φυσεως*; (Phaedr., p. 371, Ed. Bip.) (Do you think then it is possible to understand at all adequately the nature of the soul, without at the same time understanding the nature of the Whole, *i.e.*, the totality of things?) The metaphysics of nature, the metaphysics of morals, and the metaphysics of the beautiful mutually presuppose each other, and only when taken as connected together do they complete the explanation of things as they really are, and of existence in general. So that whoever should exactly trace one of these three to its ultimate origin, would be found to have necessarily brought the others into his solution of the problem; just as an absolutely clear and exhaustive understanding of any single thing in the world would imply a perfect comprehension of everything else.

Now if we were to start from a given system of metaphysics, which is assumed to be true, we should reach synthetically a basis of morals, and this basis, being, so to say, built up from below, would provide the resulting ethical structure with a sure foundation. But in the present case, since the terms of the question enforce the separation of ethics from all metaphysics, there remains nothing but the analytic method, which proceeds from facts either of external experience, or of consciousness. It is true that thus the ultimate origin of the latter may be traced back to the human spirit, a source which then, however, must be taken as a fundamental fact, a primary phaenomenon, underivable from anything else, with the result that the whole explanation remains simply a psychological one. At best its connection with any general metaphysical standpoint can only be described as accessory. On the other hand, the fundamental datum, the primary phaenomenon of Ethics, so found in man's nature, could itself in its turn be accounted for and explained, if we might first treat of metaphysics, and then by the synthetic method deduce Ethics from it. This would mean, however, nothing less than the construction of a complete system, of philosophy, whereby the limits of the given question would be far exceeded. I am, therefore, compelled to answer it within the lines which its own isolated narrowness has laid down.

And lastly, there is the following consideration. The basis on which it is here intended to place Ethics will prove to be a very small one; and the

consequence is that of the many lawful, approvable, and praiseworthy actions of mankind, only the minority will be found to spring from purely moral motives, while the majority will have to be attributed to other sources. This gives less satisfaction, has not such a specious glitter as, let us say, a Categorical Imperative, which always stands ready for commands, only that itself in its turn may command what ought to be done, and what ought to be left undone;[1] not to mention other foundations that are entirely material.

I can only, therefore, remind the reader of the saying in Ecclesiastes (iv. 6): “Better is an handful with quietness, than both the hands full with travail and vexation of spirit.” In all knowledge the genuine, proof-resisting, indestructible coefficient is never large; just as in the earth’s metallic strata a hundredweight of stone hides but a few ounces of gold. But whether others will prefer — as I do — the assured to the bulky possession, the small quantity of gold which remains in the crucible to the big lump of matter that was brought along with it; or whether I shall rather be charged with having removed from Ethics its basis, instead of providing one, in so far as I prove that the lawful and commendable actions of mankind often do not contain a particle of pure moral worth, and in most cases only a very little, resting, as they do, otherwise on motives, the sufficiency of which must ultimately be referred to the egoism of the doer; all this I must leave undecided; and I do so, not without anxiety, nay, rather with resignation, because I have long since been of the same mind as Johann Georg von Zimmermann, when he said: “Rest assured until your dying day, that nothing in the world is so rare as a good judge.” (*Ueber die Einsamkeit*; Pt. I., Ch. iii., p. 93.)

For all true and voluntary righteousness, for all loving-kindness, for all nobleness, wherever these qualities may be found, my theory can only point to a very small foundation; whereas my opponents confidently construct broad bases for Morals, which are made strong enough for every possible burden, and are at the same time thrust upon every doubter’s conscience, accompanied with a threatening side-glance at his own morality. As contrasted with these, my own position is indeed in sore and sorry plight. It is like that of Cordelia before King Lear, with her weakly worded assurance of dutiful affection, compared with the effusive protestations of her more eloquent sisters. So that there seems to be need of a cordial that may be furnished by some maxim taken from intellectual hunting grounds, such as,

Magna est vis veritatis, et praevalebit. (Great is the strength of truth, and it will prevail.) But to a man who has lived and laboured even this fails to give much encouragement. Meanwhile, I will for once make the venture with truth on my side; and what opposes me will at the same time oppose truth.

ENDNOTES.

[1] That is, the Categorical Imperative appears at first as your “obedient humble servant,” ready to perform any useful service, *e.g.*, the solving of ethical riddles; while it ends by gaining the upper hand, and commanding. — (*Translator*.)

CHAPTER II.

GENERAL RETROSPECT.

For the people morality comes through, and is founded on, theology, as the express will of God. On the other hand, we see philosophers, with few exceptions, taking special pains to entirely exclude this kind of foundation; indeed, so they may but avoid it, they prefer even to find a refuge in sophistry. Whence comes this antithesis? Assuredly no more efficient basis for Ethics can be imagined than the theological; for who would be so bold as to oppose the will of the Almighty and the Omniscient? Unquestionably, no one; if only this will were proclaimed in an authentic, official manner (if one may say so), whereby no possible room for doubt could be left. This, however, is precisely the condition which does not admit of being realised. It is rather the inverse process which is attempted. The law declared to be the will of God men try to accredit as such, by demonstrating its agreement with our own independent, and hence, natural moral views, and an appeal is consequently made to these as being more direct and certain. But this is not all. We perceive that an action performed solely through threat of punishment and promise of reward would be moral much more in appearance than in reality; since, after all, it would have its root in Egoism, and in the last resort the scale would be turned by the greater or less amount of credulity evinced in each case. Now it was none other than Kant who destroyed the foundations of Speculative Theology, which up to his time were accounted unshakable. Speculative Theology had hitherto sustained Ethics, and in order to procure for the former an existence of some sort, if only an imaginary one, his wish was to proceed inversely, and make Ethics sustain Speculative Theology. So that it is now more than ever impossible to think of basing Ethics on Theology; for no one knows any longer which of the two is to be the supporter, and which the supported, and the consequence is a *circulus vitiosus*.

It is precisely through the influence of Kant's philosophy; through the contemporaneous effect of the unparalleled progress made in all the natural sciences, with regard to which every past age in comparison with our own appears childish; and lastly, through the knowledge of Sanskrit literature, and of those most ancient and widest spread faiths, Brahmanism and Buddhism, which, as far as time and space go, are the most important

religions systems of mankind, and, as a matter of fact, are the original native religions of our own race, now well known to be of Asiatic descent — our race, to which in its new strange home they once more send a message across the centuries; — it is because of all this, I say, that the fundamental philosophical convictions of learned Europe have in the course of the last fifty years undergone a revolution, which perhaps many only reluctantly admit, but which cannot be denied. The result of this change is that the old supports of Ethics have been shown to be rotten, while the assurance remains that Ethics itself can never collapse; whence the conviction arises that for it there must exist a groundwork different from any hitherto provided, and adaptable to the advanced views of the age. The need of such is making itself felt more and more, and in it we undoubtedly find the reason that has induced the Royal Society to make the present important question the subject of a prize essay.

In every age much good morality has been preached; but the explanation of its *raison d'être* has always been encompassed with difficulties. On the whole we discern an endeavour to get at some objective truth, from which the ethical injunctions could-be logically deduced; and it has been sought for both in the nature of things, and in the nature of man; but in vain. The result was always the same. The will of each human unit was found to gravitate solely towards its own individual welfare, the idea of which in its entirety is designated by the term "blissfulness" (*Glückseligkeit*); and this striving after self-satisfaction leads mankind by a path very, different to the one morality would fain point out. The endeavour was next made now to identify "blissfulness" with virtue, now to represent it as virtue's consequence and effect. Both attempts have always failed; and this for no want of sophistry. Then recourse was had to artificial formulas, purely objective and abstract, as well *a posteriori* as *a priori*, from which correct ethical conduct undoubtedly admitted of being deduced. But there was nothing found in man's nature to afford these a footing, whereby they might have availed to guide the strivings of his volition, in face of its egoistic tendency. It appears to me superfluous to verify all this by describing and criticising every hitherto existing foundation of morality; not only because I share Augustine's opinion, *non est pro magno habendum quid homines senserint, sed quae sit rei veritas* (It is the truth about a thing, not men's opinions thereon, that is of importance); but also because it would be like *γλαύκας εἰς 'Αθήνας κομίζειν* (*i.e.*, carrying coals to Newcastle); for

previous attempts to give a foundation to Ethics are sufficiently well-known to the Royal Society, and the very question proposed shows that it is also convinced of their inadequateness. Any reader less well-informed will find a careful, if not complete, presentment of the attempts hitherto made, in Garve's *Uebersicht der vornehmsten Principien der Sittenlehre*, and again, in Stäudlin's *Geschichte der Moralphilosophie.* It is of course very disheartening to reflect that Ethics, which so directly concerns life, has met with the same unhappy fate as the abstruse science of Metaphysics, and that its first principle, though perpetually sought for ever since the time of Socrates, has still to be found. Moreover, we must remember that in Ethics, much more than in any other science, what is essential is contained in its fundamental propositions; the deductions are so simple that they come of themselves. For all are capable of drawing a conclusion, but few of judging. And this is exactly the reason why lengthy text-books and dissertations on Morals are as superfluous as they are tedious. Meantime, if I may postulate an acquaintance with all the former foundations of Ethics, my task will be lightened. Whoever observes how ancient as well as modern philosophers (the Church creed sufficed for the middle ages) have had recourse to the most diverse and extraordinary arguments, in order to provide for the generally recognised requirements of morality a basis capable of proof, and how notwithstanding they admittedly failed; he will be able to measure the difficulty of the problem, and estimate my contribution accordingly. And he who has learned to know that none of the roads hitherto struck on lead to the goal, will be the more willing to tread with me a very different path from these — a path which up to now either has not been noticed, or else has been passed over with contempt; perhaps because it was the most natural one.[1] As a matter of fact my solution of the question will remind many of Columbus' egg.

It is solely to the latest attempt at giving, a basis to Ethics — I mean the Kantian — that a critical examination will be devoted. I shall make it all the more exhaustive, partly because the great ethical reform of Kant gave to this science a foundation having a real superiority to previous ones and partly because it still remains the last important pronouncement in this domain; for which reason it has obtained general acceptance up to the present day, and is universally taught, although differently garnished by certain changes in the demonstration and in the terminology. It is the ethical

system of the last sixty years, which must be removed ere we enter on another path. Furthermore, my criticism of the Kantian basis will give me occasion to examine and discuss most of the fundamental conceptions of Ethics, and the outcome of this investigation I shall later on be able to postulate. Besides, inasmuch as opposites illustrate each other, it is exactly this course which will be the best preparation and guide, indeed the direct way, to my own position, which in its essential points is diametrically opposed to Kant's. It would therefore be a very perverse beginning to skip the following criticism, and turn at once to the positive part of my exposition, which then would remain only half intelligible.

In any case the time has assuredly arrived for once to cite Ethics before the bar of a searching scrutiny. During more than half a century it has been lying comfortably on the restful cushion which Kant arranged for it — the cushion of the Categorical Imperative of Practical Reason. In our day this Imperative is mostly introduced to us under a name which, being smoother and less ostentatious, has obtained more currency. It is called "the Moral Law"; and thus entitled, with a passing bow to reason and experience, it slips through unobserved into the house. Once inside, there is no end to its orders and commands; nor can it ever afterwards be brought to account. It was proper, indeed inevitable, that Kant, as the inventor of the thing, should remain satisfied with his creation, particularly as he shelved by its means errors still more glaring. But to be obliged to look on and see asses disporting themselves on the comfortable cushion which he prepared, and which since his time has been more and more trampled on and flattened out — this truly is hard. I allude to the daily hackney compilers, who, with the ready confidence born of stupidity, imagine that they have given a foundation to Ethics, if they do but appeal to that "Moral Law" which Is alleged to be inherent in our reason; and then they complacently weave upon this such a confused and wide-reaching tissue of phrases that they succeed in rendering unintelligible the clearest and simplest relations of life: and all this, without ever once seriously asking themselves whether in point of fact there really does exist such a "Moral Law," as a convenient code of morality, graven in our heads or hearts.

Hence I admit the especial pleasure I feel in proceeding to remove from Ethics its broad cushion of repose, and I unreservedly declare my intention of proving that Kant's Practical Reason and Categorical Imperative are completely unwarrantable, baseless, and fabricated assumptions; and I shall

further show that Kant's whole system, like those of his predecessors, is in want of a solid foundation. Consequently Ethics will again be consigned to its former entirely helpless condition, there to remain, until I come to demonstrate the true moral principle of human nature — a principle which is incontestably efficient, and has its root in our very being. The latter, however, has no such broad basis to offer as the above-mentioned cushion; so that, doubtless, those who are accustomed to take things easily, will not abandon their comfortable old seat, before they are thoroughly aware how deeply the ground on which it stands is undermined.

ENDNOTES.

1

Io dir non vi saprei per qual sventura,
O piuttosto per qual fatalità,
Da noi credito ottien più l'impostura,
Che la semplice e nuda verità.
CASTI.

[I cannot tell what mischief sly,
Or rather what fatality,
Leads man to credit more the lie
Than truth in naked purity.]

PART II. CRITIQUE OF KANT’S BASIS OF ETHICS.

CHAPTER I.

PRELIMINARY REMARKS.

It is Kant's great service to moral science that he purified it of all Eudaemonism. With the ancients, Ethics was a doctrine of Eudaemonism; with the moderns for the most part it has been a doctrine of salvation. The former wished to prove that virtue and happiness are identical; but this was like having two figures which never coincide with each other, no matter how they may be placed. The latter have endeavoured to connect the two, not by the principle of identity, but by that of causation, thus making happiness the result of virtue; but to do this, they were obliged to have recourse to sophisms, or else to assume the existence of a world beyond any possible perception of the senses.

Among the ancients Plato alone forms an exception: his system is not eudaemonistic; it is mystic, instead. Even the Ethics of the Cynics and Stoics is nothing but a special form of Eudaemonism, to prove which, there is no lack of evidence and testimony, but the nature of my present task forbids the space.[1]

The ancients, then, equally with the moderns, Plato being the single exception, agree in making virtue only a means to an end. Indeed, strictly speaking, even Kant banished Eudaemonism from Ethics more in appearance than in reality, for between virtue and happiness he still leaves a certain mysterious connection; — there is an obscure and difficult passage in his doctrine of the Highest Good, where they occur together; while it is a patent fact that the course of; virtue runs entirely counter to that of happiness. But, passing over this, we may say that with Kant the ethical principle appears as something quite independent of experience and its teaching; it is transcendental, or metaphysical. He recognises that human conduct possesses a significance that oversteps all possibility of experience, and is therefore actually the bridge leading to that which he calls the "intelligible"[2] world, the *mundus noumenôn*, the world of Things in themselves.

The fame, which the Kantian Ethics has won, is due not only to this higher level, which it reached, but also to the moral purity and loftiness of its conclusions. It is by the latter that most people have been attracted,

without paying much attention to the foundation, which is propounded in a very complex, abstract and artificial form; and Kant himself required all his powers of acumen and synthesis to give it an appearance of solidity. Fortunately, he separated his Ethics from the exposition of its basis, devoting to the latter a special work entitled the *Grundlegung zur Metaphysik der Sitten*, the theme of which will be found to be precisely the same as that of our prize essay. For on page xiii of the preface he says: "The present treatise is nothing else but an attempt to find out and establish the supreme principle of morality. This is an investigation, whose scope is complete in itself, and which should be kept apart from all other moral researches.". It is in this book that we find the basis, that is to say, the essentials of his Ethics set forth with an acute penetration and systematic conciseness, as in no other of his writings. It has, moreover, the great advantage of being the first of Kant's moral works, appearing,[3] as it did, only four years later than the *Kritik der Reinen Vernunft*, and consequently it dates from the period when, although he was sixty-one, the detrimental effect of old age on his intellect was not yet perceptible. On the other hand, this is distinctly traceable in the *Kritik der Praktischen Vernunft*, which was published in 1788, or one year later than the unhappy remodelling of the *Kritik der Reinen Vernunft* in the second edition, whereby the latter, his immortal master-piece, was obviously marred. An analysis of this question is to be found in the preface to the new edition by Rosenkranz,[4] from which my own investigation makes it impossible for me to dissent. The *Kritik der Praktischen Vernunft* contains in its essentials the same material as the above-mentioned — *Grundlegung*; only the latter has a more concise and rigorous form, while in the former the subject is handled with greater prolixity, interspersed with digressions and even padded with some pieces of moral rhetoric, to heighten the impression. When Kant wrote it, he had at last, and late in life, become deservedly famous; hence, being certain of boundless attention, he allowed greater play to the garrulity of old age.

But the *Kritik der Praktischen Vernunft* contains two sections which are peculiar to itself. First: the exposition of the relation between Freedom and Necessity (pp. 169-179 of the fourth edition, and pp. 223-231 in Rosenkranz). This passage is above all praise, and undoubtedly was framed earlier in his life, as it is entirely in harmony with his treatment of the same subject in the *Kritik der Reinen Vernunft* (pp. 560-586; Rosenkranz, p. 438, sqq.). And secondly: the *Moraltheologie*, which will more and more come

to be recognised as the real object Kant had in view. In his *Metaphysische Anfangsgründe der Tugendlehre* this *pendant* to the deplorable *Rechtslehre*, written in 1797, the debility of old age is at length fully pre-ponderant. For all these reasons the present criticism will mainly deal with the treatise first mentioned, *viz.,* the *Grundlegung zur Metaphysik der Sitten*, and the reader will please understand that all the page numbers given by themselves refer to it. Both the other works will only be considered as accessory and secondary. For a proper comprehension of the present criticism, which, in probing the Kantian Ethics to its depths, bears directly and principally on this *Grundlegung*, it is very desirable that the latter be carefully read through again, so that the mind may have a perfectly clear and fresh presentment of what it contains. It is but a matter of 128 and xiv pages (in Rosenkranz only 100 pages altogether). I shall quote from the third edition of 1792, adding the page number of the new complete publication by Rosenkranz, with an R. prefixed.

ENDNOTES.

[1] For a complete demonstration v. *Die Welt als Wille und Vorstellung*, Vol. I., § 16, p. 103, sqq., and Vol. II., Chap. 16, p. 166, sqq. of the third edition. *Die Welt als Wille und Vorstellung*, that is, *The World as Will and Idea*; "Idea" being used much as *εἴδωλον* sometimes is (cf. Xen. *Sym.,* 4, 21), in the sense of "an image in the mind," "a mental picture." — (*Translator*.)

[2] It seems better to keep this technical word than to attempt a cumbrous periphrasis. The meaning is perfectly clear. The *sensibilia* (*phaenomena*) are opposed to the *intelligibilia* (*noumena*), which compose the transcendental world. So the individual, in so far as he is a phaenomenon, has an empirical character; in so far as he is a noumenôn, his character is intelligible (*intelligibilis*). The *mundus intelligibilis,* or *mundus noumenôn* is the *κόσμος νοητὸς* of New Platonism. — (*Translator*.)

[3] It was published in 1785: *The Kritik der Reinen Vernunft,* first edition, in 1781. — (*Translator*.)

[4] His analysis is really derived from myself, but in this place I am speaking incognito.

CHAPTER II.

ON THE IMPERATIVE FORM OF THE KANTIAN ETHICS.

Kant's *πρῶτον ψεῦδος* (first false step) lies in his conception of Ethics itself, and this is found very clearly expressed on page 62 (R., p. 54): "In a system of practical philosophy we are not concerned with adducing reasons for that which takes place, but with formulating laws regarding that which ought to take place, even if it never does take place." This is at once a distinct *petitio principii.* Who tells you that there are laws to which our conduct ought to be subject? Who tells you that that ought to take place, which in fact never does take place? What justification have you for making this assumption at the outset, and consequently for forcing upon us, as the only possible one, a system of Ethics couched in the imperative terms of legislation? I say, in contradistinction to Kant, that the student of Ethics, and no less the philosopher in general, must content himself with explaining and interpreting that which is given, in other words, that which really is, or takes place, so as to obtain an understanding of it, and I maintain furthermore that there is plenty to do in this direction, much more than has hitherto been done, after the lapse of thousands of years. Following the above *petitio principii*, Kant straightway, without any previous investigation, assumes in the preface (which is entirely devoted to the subject), that purely moral laws exist; and this assumption remains thenceforth undisturbed, and forms the very foundation of his whole system. We, however, prefer first of all to examine the conception denoted by the word "law." The true and original meaning of the term is limited to law as between citizens; it is the *lex*, *νόμος*, of the Romans and Greeks, a human institution, and depending on human volition. It has a secondary, derived, figurative, metaphorical meaning, when applied to Nature, whose operations, partly known *a priori*, partly learnt by experience, and which are always constant, we call natural laws. Only a very small portion of these natural laws can be discerned *a priori*, and with admirable acuteness, Kant set them apart, and classed them under the name "Metaphysics of Nature." There is also undoubtedly a law for the human will, in so far as man belongs to Nature; and this law is strictly provable, admits of no exception, is inviolable, and immovable as the mountains, and does not, like the Categorical Imperative, imply a quasi-necessity, but rather a complete and

absolute one. It is the law of motivation, a form of the law of causation; in other words, it is the causation which is brought about by the medium of the understanding. It is the sole demonstrable law to which the human will as such is subject. It means that every action can only take place in consequence of a sufficient motive. Like causality in general, it is a natural law. On the other hand, moral laws, apart from human institution, state ordinance, or religious doctrine, cannot rightly be assumed as existing without proof. Kant, therefore, by taking such laws for granted, is guilty of a *petitio principii*, which is all the bolder, in that he at once adds (page vi of the preface) that a moral law ought to imply "absolute necessity." But "absolute necessity" is everywhere characterised by an inevitable chain of consequence; how, then, can such a conception be attached to these alleged moral laws (as an instance of which he adduces "thou shalt not lie"[1])? Every one knows, and he himself admits, that no such consecution for the most part takes place; the reverse, indeed, is the rule.

In scientific Ethics before we admit as controlling the will other laws besides that of motivation-laws which are original and independent of all human ordinance — we must first prove and deduce their existence; that is, provided in things ethical we are concerned not merely with recommending honesty, but with practising it. Until that proof be furnished, I shall recognise only one source to which is traceable the importation into Ethics of the conception Law, Precept, Obligation. It is one which is foreign to philosophy. I mean the Mosaic Decalogue. Indeed the spelling "du sollt"[2] in the above instance of a moral law, the first put forward by Kant, naïvely betrays this origin. A conception, however, which can\ point to no other source than this, has no right, without undergoing further scrutiny, thus to force its way into philosophical Ethics. It will be rejected, until introduced by duly accredited proof. Thus on the threshold of the subject Kant makes his first *petitio principii*, and that no small one.

Our philosopher, then, by begging the question in his preface, simply assumes the conception of Moral Law as given and existing beyond all doubt; and he treats the closely related conception of Duty (page 8, R., p. 16) exactly in the same way. Without subjecting it to any further test, he admits it forthwith as a proper appurtenance of Ethics. But here, again, I am compelled to enter a protest. This conception, equally with the kindred notions of Law, Command, Obligation, etc., taken thus unconditionally, has its source in theological morals, and it will remain a stranger to

philosophical morals, so long as it fails to furnish sufficient credentials drawn either from man's nature, or from the objective world. Till then, I can only recognise the Decalogue as the origin of all these connected conceptions. Since the rise of Christianity there is no doubt that philosophical has been unconsciously moulded by theological ethics. And since the latter is essentially dictatorial, the former appears in the shape of precepts and inculcation of Duty, in all innocence, and without any suspicion that first an ulterior sanction is needful for this *rôle*; rather does she suppose it to be her proper and natural form. It is true that all peoples, ages, and creeds, and indeed all philosophers (with the exception of the materialists proper) have undeniably recognised that the ethical significance of human conduct is a metaphysical one, in other words, that it stretches out beyond this phaenomenal existence and reaches to eternity; but it is equally true that the presentment of this fact in terms of Command and Obedience, of Law and Duty, is no part of its essence. Furthermore, separated from the theological hypotheses whence they have sprung, these conceptions lose in reality all meaning, and to attempt a substitute for the former by talking with Kant of absolute obligation and of unconditioned duty, is to feed the reader with empty words, nay more, is to give him a *contradictio in adjecto*[3] to digest.

Every obligation derives all sense and meaning; simply and solely from its relation to threatened punishment or promised reward. Hence, long before Kant was thought of, Locke says: "For since it would be utterly in vain, to suppose a rule set to the free actions of man, without annexing to it some enforcement of good and evil to determine his will; we must, wherever we suppose a law, suppose also some reward or punishment annexed to that law." (*Essay on the Human Understanding*, Bk. II., ch. 33, § 6). What ought to be done is therefore necessarily conditioned by punishment or reward; consequently, to use Kant's language, it is essentially and inevitably hypothetical, and never, as he maintains, categorical. If we think away these conditions, the conception of obligation becomes void of sense; hence absolute obligation is most certainly a *contradictio in adjecto.* A commanding voice, whether it come from within, or from without, cannot possibly be imagined except as threatening or promising. Consequently obedience to it, which may be wise or foolish according to circumstances, is yet always actuated by selfishness, and therefore morally worthless.

The complete unthinkableness and nonsense of this conception of an unconditioned obligation, which lies at the root of the Kantian Ethics, appears later in the system itself, namely in the *Kritik der Praktischen Vernunft*: just as some concealed poison in an organism cannot remain hid, but sooner or later must come out and show itself. For this obligation, said to be so unconditioned, nevertheless postulates; more than one condition in the background; it assumes a rewarder, a reward, and the immortality of the person to be rewarded.

This is of course unavoidable, if one really makes Duty and Obligation the fundamental conception of Ethics; for these ideas are essentially relative, and depend for their significance on the threatened penalty or the promised reward. The guerdon which is assumed to be in store for virtue shows clearly enough that only in appearance she works for nothing. It is, however, put forward modestly veiled, under the name of the Highest Good, which is the union of Virtue and Happiness. But this is at bottom nothing else but a morality that derives its origin from Happiness, which means, a morality resting on selfishness. In other words, it is Eudaemonism, which Kant had solemnly thrust out of the front door of his system as an intruder, only to let it creep in again by the postern under the name of the Highest Good. This is how the assumption of unconditioned absolute obligation, concealing as it does a contradiction, avenges itself. Conditioned obligation, on the other hand, cannot of course be any first principle for Ethics, since everything done out of regard for reward or punishment is necessarily an egoistic transaction, and as such is without any real moral value. All this makes it clear that a nobler and wider view of Ethics is needed, if we are in earnest about our endeavour to truly account for the significance of human conduct — a significance which extends beyond phaenomena and is eternal.

As all obligation is entirely dependent on a condition, so also is all duty. Both conceptions are very closely related, indeed almost identical. The only difference between them might be said to be that obligation in general may rest on mere force, whereas duty involves the sense of obligation deliberately undertaken, such as we see between master and servant, principal and subordinate, rulers and the ruled. And since no one undertakes a duty *gratis,* every duty implies also a right. The slave has no duties, because he has no rights; but he is subject to an obligation which rests on sheer force. In the following Part I shall explain the only meaning which the conception “Duty” has in Ethics.

If we put Ethics in an imperative form, making it a Doctrine of Duties, and regard the moral worth or worthlessness of human conduct as the fulfilment or violation of duties, we must remember that this view of Duty, and of Obligation in general, is undeniably derived solely from theological Morals, and primarily from the Decalogue, and consequently that it rests essentially and inseparably on the assumption of man's dependence on another will which gives him commands and announces reward or punishment. But the more the assumption of such a will is in Theology positive and precise, the less should it be quietly and unsuspectingly introduced into philosophical Morals. Hence we have no right to assume beforehand that for the latter the imperative Form, the ordaining of commands, laws, and duties is an essential and a matter of course; and it is a very poor shift to substitute the word "absolute" or "categorical" for the external condition which is indissolubly attached to such conceptions by their very nature: for this gives rise, as explained above, to a *contradictio in adjecto*.

Kant, then, without more ado or any close examination, borrowed this imperative Form of Ethics from theological Morals. The hypotheses of the latter (in other words, Theology) really lie at the root of his system, and as these alone in point of fact lend it any meaning or sense, so they cannot be separated from, indeed are implicitly contained in, it. After this, when he had expounded his position the task of developing in turn a Theology out of his Morals — the famous *Moraltheologie* — was easy enough. For the conceptions which are implicitly involved in his Imperative, and which lie hidden at the base of his Morals, only required to be brought forward and expressed explicitly as postulates of Practical Reason. And so it was that, to the world's great edification, a Theology appeared depending simply on Ethics, indeed actually derived therefrom. But this came about because the ethical system itself rests on concealed theological hypotheses. I mean no derisive comparison, but in its form the process is analogous to that whereby a conjurer prepares a surprise for us, when he lets us find something where he had previously employed his art to place it. Described in the abstract, Kant's procedure is this: what ought to have been his first principle, or hypothesis (*viz*., Theology) he made the conclusion, and what ought to have been deduced as the conclusion (*viz*., the Categorical Command) he took as his hypothesis.[4] But after he had thus turned the thing upside down, nobody, not even he himself, recognised it as being what it

really was, namely the old well-known system of theological Morals. How this trick was accomplished we shall consider in the sixth and seventh chapters of the present Part.

Ethics was of course frequently put in the imperative form, and treated as a doctrine of duties also in pre-Kantian philosophy; but it was always then based upon the will of a God whose existence had been otherwise proved, and so there was no inconsequence. As soon, however, as the attempt was made, as Kant attempted, to give a foundation to Ethics independent of this will, and establish it without metaphysical hypotheses, there was no longer any justification for taking as its basis the words "thou shalt," and "it is thy duty" (that is, the imperative form), without first deducing the truth thereof from some other source.

ENDNOTES.

[1] Du sollt (*sic*) nicht lügen.

[2] Sollt is the old form for “*sollst*.” Cf. Eng., *shalt*: Icel; *skalt* — (*Translator*.)

[3] A contradiction in the adjective. This occurs when the epithet applied to a noun contradicts its essential meaning. — (*Translator*.)

[4] Like the converse of a geometrical proposition, this Kantian inversion is not necessarily true; its validity, in fact, depends on the conclusion being implicitly contained in the hypothesis. — (*Translator*.)

CHAPTER III.

ON THE ASSUMPTION OF DUTIES TOWARDS OURSELVES IN PARTICULAR.

This form of the doctrine of duties was very acceptable to Kant, and in working out his position he left it untouched; for, like his predecessors, along with the duties towards others he ranged also duties towards ourselves. I, however, entirely reject this assumption, and, as there will be no better opportunity, I shall here incidentally explain my view.

Duties towards ourselves must, just as all others, be based either on right or on love. Duties towards ourselves based on right are impossible, because of the self-evident fundamental principle *volenti non fit injuria* (where the will assents, no injury is done). For what I do is always what I will; consequently also what I do to myself is never anything but what I will, therefore it cannot be unjust. Next, as regards duties towards ourselves based on love. Ethics here finds her work already done, and comes too late. The impossibility of violating the duty of self-love is at once assumed by the first law of Christian Morals: "Love thy neighbour as thyself." According to this, the love which each man cherishes for himself is postulated as the *maximum*, and as the condition of all other love; while the converse, "Love thyself as thy neighbour" is never added; for every one would feel that the latter does not claim enough. Moreover, self-love would be the sole duty regularly involving an *opus supererogationis*. Kant himself says in the *Metaphysische Anfangsgründe zur Tugendlehre*, p. 13 (R., p. 230): "That which each man inevitably wills of himself, does not belong to the conception of Duty." This idea of duties towards ourselves is nevertheless still held in repute, indeed it enjoys for the most part special favour; nor need we feel surprise. But it has an amusing effect in cases where people begin to show anxiety about their persons, and talk quite earnestly of the duty of self-preservation; the while it is sufficiently clear that fear will lend them legs soon enough, and that they have no need of any law of duty to help them along.

First among the duties towards ourselves is generally placed that of not committing suicide, the line of argument taken being extremely prejudiced and resting on the shallowest basis. Unlike animals, man is not only a prey to bodily pain limited to the passing moment, but also to those

incomparably greater mental sufferings, which, reaching forwards and backwards, draw upon the future and the past; and nature, by way of compensation, has granted to man alone the privilege of being able to end his life at his own pleasure, before she herself sets a term to it; thus, while animals necessarily live so long as they can, man need only live so long as he will.

Whether he ought on ethical grounds to forego this privilege is a difficult question, which in any case cannot be decided by the usual superficial reasoning. The arguments against suicide which Kant does not deem unworthy of adducing (p. 53, R., p. 48 and p. 67, R., p. 57), I cannot conscientiously describe as other than pitiable, and quite undeserving of an answer. It is laughable indeed to suppose that reflections of such a kind could have wrested the dagger from the hands of Cato, of Cleopatra, of Cocceius Nerva (Tac. *Ann*., vi. 26) or of Arria the wife of Paetus (Plin., *Ep*., iii. 16). If real moral motives for not committing suicide actually exist, it is certain that they lie very deep, and cannot be reached by the plummet of ordinary Ethics. They belong to a higher view of things than is adaptable even to the standpoint of the present treatise.[1]

That which generally comes next on the rubric of duties towards ourselves may be divided partly into rules of worldly wisdom, partly into hygienic prescriptions; but neither class belongs to Morals in the proper sense. Last on the catalogue comes the prohibition of unnatural lust — onanism, *paederastia,* and bestiality. Of these onanism is mainly a vice of childhood, and must be fought against much more with the weapon of dietetics than with that of ethics; hence we find that the authors of books directed against it are physicians (*e.g.*, Tissot and others) rather than moralists. After dietetics and hygiene have done their work, and struck it down by irrefutable reasoning, if Ethics desires to take up the matter, she finds little left for her to do. Bestiality, again, is of very rare occurrence; it is thoroughly abnormal and exceptional, and, moreover, so loathsome and foreign to human nature, that itself, better than all arguments of reason, passes judgment on itself, and deters by sheer disgust. For the rest, as being a degradation of human nature, it is in reality an offence against the species as such, and in the abstract; not against human units. Of the three sexual perversions of which we are speaking it is consequently only with *paederastia* that Ethics has to do, and in treating of Justice this vice finds its

proper place. For Justice is infringed by it, in face of which fact, the dictum *volenti non fit injuria* is unavailing. The injustice consists in the seduction of the younger and inexperienced person, who is thereby ruined physically and morally.

ENDNOTES.

[1] There are ascetic reasons, which may be found in the Fourth Book, Vol. I., § 69, of my chief work (*Die Welt als Wille und Vorstellung*).

CHAPTER IV.

ON THE BASIS OF THE KANTIAN ETHICS.

With the imperative Form of Ethics, which in Chapter II. we proved to be a *petitio principii*, is directly connected a favourite idea of Kant's, that may be excused, but cannot be adopted. Sometimes we see a physician, after having employed a certain remedy with conspicuous success, henceforth prescribing it for almost all diseases; to such a one Kant may be likened. By separating the *a priori* from the *a posteriori* in human knowledge he made the most brilliant and pregnant discovery that Metaphysics can boast of. What wonder then that thereafter he should try to apply this method, this sundering of the two forms, everywhere, and should consequently make Ethics also consist of two parts, a pure, *i.e.* an *a priori* knowable part, and an empirical? The latter of these he rejects as unreliable for the purpose of founding Ethics. To trace out the former and; exhibit it by itself is his purpose in the *Grundlegung der Metaphysik der Sitten*, which he accordingly represents as a science purely *a priori*, exactly in the same way as he sets forth the *Metaphysische Anfangsgründe der Naturwissenschaft*. He asserts in fact that the Moral Law, which without warrant, without deduction, or proof of any sort, he postulates as existing, is furthermore a Law knowable *a priori* and independent of all internal or external experience; it "*rests*" (he says) "solely on conceptions of pure Reason; and is to be taken as a synthetic proposition a priori" (*Kritik der Praktischen Vernunft*: p. 56 of fourth Edition; R., p. 142). But from this definition the implication immediately follows that such a Law can only be formal, like everything else known *a priori*, and consequently has only to do with the Form of actions, not with their Essence. Let it be thought what this means! He emphatically adds (p. vi of the preface to the *Grundlegung;* R., p. 5) that it is "useless to look for it either subjectively in man's nature, or objectively in the accidents of the external world," and (preface of the same, page vii; R., p. 6) that "nothing whatever connected with it can be borrowed from knowledge relating to man, *i.e.*, from anthropology." On page 59 (R., p. 52) he repeats, "That one ought on no account to fall into the mistake of trying to derive one's principle of morality from the special constitution of human nature"; and again, on page 60 (R., p. 52), he says that, "Everything derived from any natural disposition peculiar to man, or from certain feelings and

propensities, or indeed from any special trend attaching solely to human nature, and not necessarily to be taken as the Will of every rational being," is incapable of affording a foundation for the moral law. This shows beyond all possibility of contradiction that Kant does not represent the alleged moral law as a *fact of consciousness*, capable of empirical proof — which is how the later would-be philosophers, both individually and collectively, wish to pass it off. In discarding every empirical basis for Morals, he rejects all internal, and still more decidedly all external, experience., Accordingly he founds — and I call special attention to this — his moral principle not on any provable *fact of consciousness*, such as an inner natural disposition, nor yet upon any objective relation of things in the external world. No! That would be an empirical foundation. Instead of this, *pure conceptions a priori*, *i.e.*, conceptions, which so far contain nothing derived from internal or external experience, and thus are simply shells without kernels — these are to be made the basis of Morals. Let us consider the full meaning of such a position. Human consciousness as well as the whole external world, together with all the experience and all the facts they comprise, are swept from under our feet. We have nothing to stand upon. And what have we to hold to? Nothing but a few entirely abstract, entirely unsubstantial conceptions, floating in the air equally with ourselves. It is from these, or, more correctly, from the mere form of their connection with judgments made, that a *Law* is declared to proceed, which by so-called absolute necessity is supposed to be valid, and to be strong enough to lay bit and bridle on the surging throng of human desires, on the storm of passion, on the giant might of *egoism*. We shall see if such be the case.

With this preconceived notion that the basis of Morals must be necessarily and strictly a priori, and entirely free from everything empirical, another of Kant's favourite ideas is closely connected. The moral principle that he seeks to establish is, he says, a synthetic proposition a priori, of merely formal contents, and hence exclusively a matter of Pure Reason; and accordingly, as such, to be regarded as valid not only for men, but for all possible rational beings; indeed he declares it to hold good for man "on this account alone," *i.e.*, because *per accidens* man comes under the category of rational beings. Here lies the cause of his basing the Moral principle not on any feeling, but on pure Reason (which knows nothing but itself and the statement of its antithesis). So that this pure Reason is taken, not as it really and exclusively is — an intellectual faculty of man — but as a self-existent

hypostatic essence, yet without the smallest authority; the pernicious effects of such example and precedent being sufficiently shown in the pitiful philosophy of the present day. Indeed, this view of Morals as existing not for men, as men, but for all rational beings, as such, is with Kant a principle so firmly established, an idea so favourite, that he is never tired of repeating it at every opportunity.

I, on the contrary, maintain that we are never entitled to raise into a *genus* that which we only know of in a single species. For we could bring nothing into our idea of the *genus* but what we had abstracted from this one species; so that what we should predicate of the *genus* could after all only be understood of the single species. While, if we should attempt to think away (without any warrant) the particular attributes of the species, in order to form our *genus*, we should perhaps remove the exact condition whereby the remaining attributes, hypostatised as a *genus*, are made possible. Just as we recognise intelligence in general to be an attribute of animal beings alone, and are therefore never justified in thinking of it as existing outside, and independent, of animal nature; so we recognise Reason as the exclusive attribute of the human race, and have not the smallest right to suppose that Reason exists externally to it, and then proceed to set up a *genus* called "Rational Beings," differing from its single known species "Man"; still less are we warranted in laying down laws for such imaginary rational beings in the abstract. To talk of rational beings external to men is like talking of heavy beings external to bodies. One cannot help suspecting that Kant was thinking a little of the dear cherubim, or at any rate counted on their presence in the conviction of the reader. In any case this doctrine contains a tacit assumption of an *anima rationalis,* which as being entirely different from the *anima sensitiva*, and the *anima vegetativa*, is supposed to persist after death, and then to be indeed nothing else but *rationalis*. But in the *Kritik der Reinen Vernunft* Kant himself has expressly and elaborately made an end of this most transcendent hypostasis. Nevertheless, in his ethics generally, and in the *Kritik der Praktischen Vernunft* especially, there seems always to hover in the background the thought that the inner and eternal essence, of man consists of Reason. In this connection, where the matter only occurs incidentally, I must content myself with simply asserting the contrary. Reason, as indeed the intellectual faculty as a whole, is secondary, is an attribute of phaenomena, being in point of fact conditioned by the

organism; whereas it is the Will in man which is his very self, the only part of him which is metaphysical, and therefore indestructible.

The success with which Kant had applied his method to the theoretical side of philosophy led him on to extend it to the practical. Here also he endeavoured to separate pure *a priori* from empirical *a posteriori* knowledge. For this purpose he assumed that just as we know *a priori* the laws of Space, of Time, and of Causality, so in like manner, or at any rate analogously, we have the moral plumb-line for our conduct given us prior to all experience, and revealed in a Categorical Imperative, an absolute "Ought." But how wide is the difference between this alleged moral law *a priori*, and our theoretical knowledge *a priori* of Space, Time, and Causality! The latter are nothing but the expression of the forms, *i.e.*, the functions of our intellect, whereby alone we are capable of grasping an objective world, and wherein alone it can be mirrored; so that the world (as we know it) is absolutely conditioned by these forms, and all experience must invariably and exactly correspond to them — just as everything that I see through a blue glass must appear blue. While the former, the so-called moral law, is something that experience pours ridicule on at every step; indeed, as Kant himself says, it is doubtful whether in practice it has ever really been followed on any single occasion. How completely unlike are the things which are here classed together under the conception of apriority! Moreover, Kant overlooked the fact that, according to his own teaching, in theoretical philosophy, it is exactly the Apriority of our knowledge of Time, Space, and Causality — independent as this is of experience — that limits it strictly to phaenomena, *i.e.*, to the picture of the world as reflected in our consciousness, and makes it entirely invalid as regards the real nature of things, *i.e.*, as regards whatever exists independently of our capacity to grasp it.

Similarly, when we turn to practical philosophy, his alleged moral law, if it have an *a priori* origin in ourselves, must also be only phaenomenal, and leave entirely untouched the essential nature of things. Only this conclusion would stand in the sharpest contradiction as much to the facts themselves, as to Kant's view of them. For it is precisely the moral principle in us that he everywhere (*e.g., Kritik der Praktischen Vernunft*, p. 175; R., p. 228) represents as being in the closest connection with the real essence of things, indeed, as directly in contact with it; and in all passages in the *Kritik der Reinen Vernunft,* where the mysterious Thing in itself comes forward a little

more clearly, it shows itself as the moral principle in us, as Will. But of this he failed to take account.

In Chapter II. of this Part, I explained how Kant took over bodily from theological Morals the imperative form of Ethics, *i.e.*, the conception of obligation, of law, and of duty; and how at the same time he was constrained to leave behind that which in the realm of theology alone lends force and significance to these ideas. But he felt the need of some basis for them, and accordingly went so far as to require that the *conception of duty* itself should be also the *ground of its fulfilment*; in other words, that it should itself be its own enforcement. An action, he says (p. 11; R., p. 18), has no genuine moral worth, unless it be done simply as a matter of duty, and for duty's sake, without any liking for it being felt; and the character only begins to have value, if a man, who has no sympathy in his heart, and is cold and indifferent to others' sufferings, and who is not by nature a lover of his kind, is nevertheless a doer of good actions, solely out of a pitiful sense of duty. This assertion, which is revolting to true moral sentiment; this apotheosis of lovelessness, the exact opposite, as it is, of the Christian doctrine of Morals, which places love before everything else, and teaches that without it nothing profiteth (1 Cor. xiii. 3); this stupid moral pedantry has been ridiculed by Schiller in two apposite epigrams, entitled *Gewissensskrupel* (Scruples of Conscience) and *Entscheidung* (Decision).[1]

It appears that some passages in the *Kritik der Praktischen Vernunft*, which exactly suit this connection, were the immediate occasion of the verses. Thus, for instance, on p. 150 (R., p. 211) we find: "Obedience to the moral law, which a man feels incumbent on him, is based not on voluntary inclination, nor on endeavour willingly put forth, without any authoritative command, but on a sense of duty." Yes, it must be commanded! What slavish morality! And again on p. 213 (R., p. 257): "Feelings of compassion, and of tender-hearted sympathy would be actually troublesome to persons who think aright, because through such emotions their well weighed maxims would become confused, and so the desire would grow up to be rid of them, and to be subject solely to the lawgiver — Reason." Now I maintain without hesitation that what opens the hand of the above-described (p. 11; R., p. 18) loveless doer of good, who is indifferent to the sufferings of other people, cannot (provided he have no secondary motives) be anything else than a slavish *δεισιδαιμονία* (fear of the gods), equally

whether he calls his fetich "Categorical Imperative" or Fitzlipuzli.[2] For what but fear can move a hard heart?

Furthermore, on p. 13 (R., p. 19), in accordance with the above view, we find that the moral worth of an action is supposed to lie, by no means in the intention which led to it, but in the maxim which was followed. Whereas I, on the contrary, ask the reader to reflect that it is the intention alone which decides as to the moral worth, or worthlessness, off an action, so that the same act may deserve condemnation or praise according to the intention which determined it. Hence it is that, whenever men discuss a proceeding to which some moral importance is attached, the intention is always investigated, and by this standard alone the matter is judged; as, likewise, it is in the *intention* alone that every one seeks justification, if he see his conduct misinterpreted or excuse, if its consequence be mischievous.

On p. 14 (R., p. 20) we at last reach the definition of Duty, which is the fundamental conception of Kant's entire ethical system. It is: "The necessity of an action out of respect for the law." But what is necessary takes place with absolute certainty while conduct based on pure duty generally does not come off at all. And not only this; Kant himself admits (p. 25; R., p. 28) that there are no certain instances on record of conduct determined solely by pure duty; and on p. 26 (R., p. 29) he says: "It is utterly impossible to know with certainty from experience whether there has ever really been one single case in which an action, however true to duty, has rested simply on its idea." — And similarly on p. 28 (R., p. 30) and p. 49 (R., p. 50). In what sense then can necessity be attributed to such an action? As it is only fair always to put the most favourable interpretation on an author's words, we will suppose him to mean that an act true to duty is objectively necessary, but subjectively accidental. Only it is precisely this that is more easily said than thought for where is the Object of this objective necessity, the consequence of which for the most part, perhaps indeed always, fails to be realised in objective reality! With every wish to be unbiassed, I cannot but think that the expression — necessity of an action — is nothing but an artificially concealed, very forced paraphrase of the word "ought."[3] This will become clearer if we notice that in the same definition the word *Achtung* (respect) is employed, where *Gehorsam* (obedience) is meant. Similarly in the note on p. 16 (R., p. 20) we read: "*Achtung* signifies simply the subordination of my will to a law. The direct determination of the will by a law, and the consciousness that it is so determined — this is what is

denoted by *Achtung*" In what language? In German the proper term is *Gehorsam*. But the word *Achtung*, so unsuitable as it is, cannot without a reason have been put in place of the word *Gehorsam.* It must serve some purpose; and this is obviously none other than to veil the derivation of the imperative form, and of the conception of duty, from theological Morals; just as we saw above that the expression "necessity of an action," which is such a forced and awkward substitute for the word "shall," was only chosen because "shall" is the exact language of the Decalogue. The above definition: "Duty is the necessity of an action out of respect for the law," would therefore read in natural, undisguised, plain language: "Duty signifies an action which ought to be done out of obedience to a law." This is "the real form of the poodle."[4]

But now as to the Law, which is the real foundation stone of the Kantian Ethics. What does it contain? And where is it inscribed? This is the chief point of inquiry. In the first place, be it observed that we have two questions to deal with: the one has to do with the Principle, the other with the Basis of Ethics — two entirely different things, although they are frequently, and sometimes indeed intentionally, confused.

The principle or main proposition of an ethical system is the shortest and most concise definition of the line of conduct which it prescribes, or, if it have no imperative form, of the line of conduct to which it attaches real moral worth. It thus contains, in the general terms of a single enunciation, the direction for following the path of virtue, which is derived from that system: in other words, it is the *ὅ,τι*[5] of virtue. Whereas the Basis of any theory of Ethics is the *διότι*[6] of virtue, the reason of the obligation enjoined, of the exhortation or praise given, whether it be sought in human nature, or in the external conditions of the world, or in anything else. As in all sciences, so also in Ethics the *ὅ,τι* must be clearly distinguished from the *διότι*. But most teachers of Morals wilfully confound this difference: probably because the *ὅ,τι* is so easy, the *διότι* so exceedingly difficult, to give. They are therefore glad to try to make up for the poverty on the one hand, by the riches on the other, and to bring about a happy marriage between *Πενία* (poverty) and *Πόρος* (plenty), by putting them together in one proposition.[7] This is generally done by taking the familiar *ὅ,τι* out of the simple form in which it can be expressed, and forcing it into an artificial formula, from which it is only to be deduced as the conclusion of given premises; and the reader is led by this performance to feel as if he had

grasped not only the thing, but its cause as well. We may easily convince ourselves of this by recalling all the most familiar principles of Morals. As, however, in what follows I have no intention of imitating acrobatic tricks of this sort, but purpose proceeding with all honesty and straightforwardness, I cannot make the principle of Ethics equivalent to its basis, but must keep the two quite separate. Accordingly, this *ὅ,τι* — *i.e.*, the principle, the fundamental proposition — as to which in its essence all teachers of Morals are really at one, however much they may clothe it in different costumes, I shall at once express in the form which I take to be the simplest and purest possible, *viz.: Neminem laede, immo omnes, quantum potes, juva*. (Do harm to no one; but rather help all people, as far as lies in your power.) This is in truth the proposition which all ethical writers expend their energies in endeavouring to account for. It is the common result of their manifold and widely differing deductions; it is the *ὅ,τι* for which the *διότι* is still sought after; the consequence, the cause of which is wanting. Hence it is itself nothing but the *Datum* (the thing given), in relation to which the *Quaesitum* (the thing required) is the problem of every ethical system, as also of the present prize essay. The solution of this riddle will disclose the real foundation of Ethics, which, like the philosopher's stone, has been searched for from time immemorial. That the *Datum*, the *ὅ,τι*, the principle is most purely expressed by the enunciation I have given, can be seen from the fact that it stands to every other precept of Morals as a conclusion to given premises, and therefore constitutes the real goal it is desired to attain; so that all other ethical commandments can only be regarded as paraphrases, as indirect or disguised statements, of the above simple proposition. This is true, for instance, even of that trite and apparently elementary maxim: *Quod tibi fieri non vis, alteri ne feceris*[8] (Do not to another what you are unwilling should be done to yourself.) The defect here is that the wording only touches the duties imposed by law, not those required by virtue; — a thing which can be easily remedied by the omission of *non* and *ne*. Thus changed, it really means nothing else than: *Neminem laede, immo omnes, quantum potes, juva.* But as this sense is only reached by a periphrasis, the formula gains the appearance of having also revealed its own ultimate foundation, its *διότι*; which, however, is not the case, because it does not in the least follow that, if I am unwilling that something be done to myself, I ought not to do it to others. The same is true of every other principle or leading proposition of Ethics that has hitherto been put forward.

If we now return to the above question: — how does the law read, in obeying which, according to Kant, duty consists? and on what is it based? — we shall find that our philosopher, like most others, has in an extremely artificial manner closely connected the principle of Morals with its basis. I again call attention to what I have already examined at the outset — I mean, the Kantian claim that the principle of Ethics must be purely *a priori* and purely formal, indeed an *a priori* synthetical proposition, which consequently may not contain anything material, nor rest upon anything empirical, whether objectively in the external world, or subjectively in consciousness, such as any feeling, inclination, impulse, and the like. Kant was perfectly aware of the difficulty of this position; for on p. 60 (R., p. 53) he says: "It will be seen that philosophy has here indeed reached a precarious standpoint, which yet is to be immovable, notwithstanding that it is neither dependent on, nor supported by, anything in heaven or on earth." We shall therefore with all the greater interest and curiosity await the solution of the problem he has set himself, namely, how something is to arise out of nothing, that is, how out of purely *a priori* conceptions, which contain nothing empirical or material, the laws of material human action are to grow up. This is a process which we may find symbolised in chemistry, where out of three invisible gases (Azote, Hydrogen, and Chlorine[9]), and thus in apparently empty space, solid sal-ammoniac is evolved before our eyes.

I will, however, explain, more clearly than Kant either would or could, the method whereby he accomplishes this difficult task. The demonstration is all the more necessary because what he did appears to be seldom properly understood. Almost all Kant's disciples have fallen into the mistake of supposing that he presents his Categorical Imperative directly as a fact of consciousness. But in that case its origin would be anthropological, and, as resting on experience, although internal, it would have an empirical basis: a position which runs directly counter to the Kantian view, and which he repeatedly rejects. Thus on p. 48 (R., p. 44) he says: "It cannot be empirically determined whether any such Categorical Imperative exists everywhere"; and again, on p. 49 (R., p. 45): "The possibility of the Categorical Imperative must be investigated entirely on *a priori* grounds, because here we are not helped by any testimony of experience as to its

reality.” Even Reinhold, his first pupil, missed this point; for in his *Beitrage zur Uebersicht der Philosophie am Anfange des* 19. *Jahrhunderts*, No. 2, p. 21, we find him saying: “Kant assumes the moral law to be a direct and certain reality, an original fact of the moral consciousness.” But if Kant had wished to make the Categorical Imperative a fact of consciousness, and thus give it an empirical foundation, he certainly would not have failed at least to put it forward as such. And this is precisely what he never does. As far as I know, the Categorical Imperative appears for the first time in the *Kritik der Reinen Vernunft* (p. 802 of the first, and p. 830 of the fifth edition), entirely ex nunc (unexpectedly), without any preamble, and merely connected with the preceding sentence by an altogether unjustifiable “therefore.”; It is only in the *Grundlage zur Metaphysik der Sitten* — a book to which we here devote especial attention — that it is first introduced expressly and formally, as a deduction from certain concepts. Whereas in Reinhold’s *Formula concordiae des Kriticismus*,[10] we actually read on p. 122 the following sentence: “We distinguish moral self-consciousness from the experience with which it, as an original fact transcending all knowledge, is bound up in the human consciousness; and we understand by such self-consciousness the direct consciousness of duty, that is, of the necessity we are under of admitting the legitimacy — whether pleasurable or the reverse — of the will, as the stimulus and as the measure of its own operations.”

This would of course be “a charming *thesis*, with a very pretty *hypothesis* to boot.”[11] But seriously: into what an outrageous *petitio principii* do we find Kant’s moral law here developed! If that were true, Ethics would indubitably have a basis of incomparable solidity, and there would be no need of any questions being set for prize essays, to encourage inquiry in this direction. But the greatest marvel would be, that men had been so slow in discovering such a fact of consciousness, considering that for the space of thousands of years a basis for Morals has been sought after with zealous patient toil. How Kant himself is responsible for this deplorable mistake, I shall explain further on; nevertheless, one cannot but wonder at the undisputed predominance of such a radical error among his disciples. Have they never, whilst writing all their numberless books on the Kantian philosophy, noticed the disfigurement which the *Kritik der Reinen Vernunft* underwent in the second edition, and which made it an incoherent, self-contradictory work? It seems that this has only now come to light; and, in my opinion, the fact has been quite correctly analysed in Rosenkranz’s

preface to the second volume of his complete edition of Kant's works. We must, however, remember that many scholars, being unceasingly occupied as teachers and authors, find very little time left for private and exact research. It is certain that *docendo disco* (I learn by teaching) is not unconditionally true; sometimes indeed one is tempted to parody it by saying: *semper docendo nihil disco* (by always teaching I learn nothing); and even what Diderot puts into the mouth of Rameau's nephew is not altogether without reason: "'And as for these teachers, do you suppose they understand the sciences they give instruction in? Not a bit of it, my dear sir, not a bit of it. If they possessed sufficient knowledge to be able to teach them, they would not do so.' 'Why?' 'Because they would have devoted their lives to the study of them.'" — (Goethe's translation, p. 104.) Lichtenberg too says: "I have rather observed that professional people are often exactly those who do not know best." But to return to the Kantian Ethics: most persons, provided only the conclusion reached agrees with their moral feelings, immediately assume that there is no flaw to be found in its derivation; and if the process of deduction looks difficult, they do not trouble themselves much about it, but are content to trust the faculty.

Thus the foundation which Kant gave to his moral law by no means consists in its being proved empirically to be a fact of consciousness; neither does he base it on an appeal to moral feeling, nor yet on a *petitio principii*, under its fine modern name of an "absolute Postulate." It is formed rather of a very subtle process of thought, which he twice advances, on p. 17 and p. 51 (R., p. 22, and p. 46), and which I shall now proceed to make clear.

Kant, be it observed, ridiculed all empirical stimuli of the will, and began by removing everything, whether subjective or objective, on which a law determining the will's action could be empirically based. The consequence is, that he has nothing left for the substance of his law but simply its Form. Now this can only be the abstract conception of lawfulness. But the conception of lawfulness is built up out of what is valid for all persons equally. Therefore the substance of the law consists of the conception of what is universally valid, and its contents are of course nothing else than its universal validity. Hence the formula will read as follows: "Act only in accordance with that precept which you can also wish should be a general law for all rational beings." This, then, is the real foundation — for the most part so greatly misunderstood — which Kant constructed for his principle

of Morals, and therefore for his whole ethical system. Compare also the *Kritik der Praktischen Vernunft*, p. 61 (R., p. 147); the end of Note 1.

I pay Kant a tribute of sincere admiration for the great acumen he displayed in carrying out this dexterous feat, but I continue in all seriousness my examination of his position according to the standard of truth. I will only observe — and this point I shall take up again later on — that here reason, because, and in so far as, it works out the above explained special ratiocination, receives the name of practical reason. Now the Categorical Imperative of Practical Reason is the law which results from this process of thought. Consequently Practical Reason is not in the least what most people, including even Fichte, have regarded it — a special faculty that cannot be traced to its source, a *qualitas occulta*, a sort of moral instinct, like Hutcheson's "moral sense"; but it is (as Kant himself in his preface, p. xii. [R., p. 8], and elsewhere, often enough declares) one and the same with theoretical reason — is, in fact, theoretical reason itself, in so far as the latter works out the ratiocinative process I have described. It is noticeable that Fichte calls the Categorical Imperative of Kant an absolute Postulate (*Grundlage der gesammten Wissenschaftslehre*, Tübingen, 1802, p. 240, Note). This is the modern, more showy, expression for *petitio principii*, and thus we see that he, too, regularly accepted the Categorical Imperative, and consequently must be included among those who have fallen into the mistake above criticised.

The objection, to which this Kantian basis of Morals is at once and directly exposed, lies in the fact that such an origin of a moral law in us is impossible, because of its assumption that man would quite of his own accord hit on the idea of looking about for, and inquiring after, a law to which his will should be subject, and which should shape its actions. This procedure, however, cannot possibly occur to him of itself; at best it could only be after another moral; stimulus had supplied the first impulse and motive thereto; and such a stimulus would have to be positively operative, and real; and show itself to be such, as well as spontaneously influence, indeed force its presence upon, the mind. But anything of this sort would run counter to Kant's assumption, which, according to the chain of reasoning above described, is to be regarded as itself the origin of all moral conceptions — in fact, the *punctum saliens* of Morality. Consequently, as long as there is no such antecedent incentive (because, *ex hypothesi*, there

exists no other moral stimulus but the process of thought already explained), so long Egoism alone must remain as the plumb-line of human conduct, as the guiding thread of the law of motivation; so long the entirely empirical and egoistic motives of the moment, alone and unchecked, must determine, in each separate case, the conduct of a man; since, on this assumption, there is no voice to arrest him, neither does any reason whatever exist, why he should be minded to inquire after, to say nothing of anxiously searching for, a law which should limit and govern his will. And yet it is only possible on this supposition that he should think out the above remarkable piece of mental legerdemain. It matters not how far we may care to put a strict and exact interpretation on this Kantian process, or whether we choose to tone it down to some dim, obscurely felt operation of thought. No modification of it can attack the primary truths that out of nothing, nothing comes, and that an effect requires a cause. The moral stimulus, like every motive that effects the will, must in all cases make itself felt spontaneously, and therefore have a positive working, and consequently be real. And because for men the only thing which has reality is the empirical, or else that which is supposed to have a possibly empirical existence, therefore it follows that the moral stimulus cannot but be empirical, and show itself as such of its own accord; and without waiting for us to begin our search, it must come and press itself upon us, and this with such force that it may, at least possibly, overcome the opposing egoistic motives in all their giant strength. For Ethics has to do with actual human conduct, and not with the *a priori* building of card houses — a performance which yields results that no man would ever turn to in the stern stress and battle of life, and which, in face of the storm of our passions, would be about as serviceable as a syringe in a great fire.

I have already noticed above how Kant considered it a special merit of his moral law that it is founded solely on abstract, pure *a priori* conceptions, consequently on pure reason; whereby its validity obtains (he says) not only for men, but for all rational beings as such. All the more must we regret that pure, abstract conceptions *a priori*, without real contents, and without any kind of empirical basis can never move, at any rate, men; of other rational beings I am of course incapable of speaking. The second defect, then, in Kant's ethical basis is its lack of real substance. So far this has escaped notice, because the real nature of his foundation has in all probability been thoroughly understood only by an exceedingly small

number of those who were its enthusiastic propagandists. The second fault, I repeat, is entire want of reality, and hence of possible efficacy. The structure floats in the air, like a web of the subtlest conceptions devoid of all contents; it is based on nothing, and can therefore support nothing, and move nothing. And yet Kant loaded it with a burden of enormous weight, namely, the hypothesis of the Freedom of the Will. In spite of his oft declared conviction that freedom in human action has absolutely no place; that theoretically not even its possibility is thinkable (*Kritik der Praktischen Vernunft*, p. 168; R., p. 223); that, if the character of a man, and all the motives which work on him were exactly known, his conduct could be calculated as certainly and as precisely as an eclipse of the moon (*ibidem*, p. 177; R., p. 230): he nevertheless makes an assumption of freedom (although only *idealiter*, and as a postulate) by his celebrated conclusion: "You can, because you ought"; and this on the strength of his precious ethical basis, which, as we see, floats in the air incorporeal. But if it has once been clearly recognised that a thing is not, and cannot be, what is the use of all the postulates in the world? It would be much more to the purpose to cast away that on which the postulate is based, because it is an impossible supposition; and this course would be justified by the rule *a non posse ad non esse valet consequentia*;[12] and by a *reductio ad absurdum*, which would at the same time be fatal to the Categorical Imperative. Instead of which one false doctrine is built up on the other.

The inadmissibility of a basis for Morals consisting of a few entirely abstract and empty conceptions must have been apparent to Kant himself in secret. For in the *Kritik der Praktischen Vernunft*, where (as I have already said) he is not so strict and methodical in his work, and where we find him becoming bolder on account of the fame he had gained, it is remarkable how the ethical basis gradually changes its nature, and almost forgets that it is a mere web of abstract ideas; in fact, it seems distinctly desirous of becoming more substantial. Thus, for instance, on p. 81 (R., p. 163) of the above work are the words: "The Moral Law in some sort a fact of Pure Reason." What is one to think of this extraordinary expression? In every other place that which is fact is opposed to what is knowable by pure reason. Similarly on p. 83 (R., p. 164) we read of "a Reason which directly determines the Will"; and so on.

Now let us remember that in laying his foundation Kant expressly and repeatedly rejects every anthropological basis, everything that could prove

the Categorical Imperative to be a fact of consciousness, because such a proof would be empirical. Nevertheless, his successors were so emboldened by incidental utterances like the above that they went to much greater lengths. Fichte in his work, *System der Sittenlehre*, p. 49, warns us expressly "not to allow ourselves to be misled into trying to explain, and derive from external sources, the consciousness that we have duties, because this would be detrimental to the dignity and absoluteness of the law." A very nice excuse! Again on p. 66 he says: "The principle of Morality is a thought which is based on the intellectual intuition of the absolute activity of the intelligence, and which is directly conceived by the pure intelligence of its own accord." What a fine flourish to conceal the helplessness of this clap-trap! Whoever may like to convince himself how Kant's disciples, little by little, totally forgot and ignored the real nature of the foundation and derivation which their master originally gave to the moral law, should read a very interesting essay in Reinhold's *Beitrage zur Uebersicht der Philosophie im Anfange des* 19. *Jahrhunderts*, No. 2, 1801. In it, on pp. 105 and 106, it is maintained "that in the Kantian philosophy Autonomy (which is the same thing as the Categorical Imperative) is a fact of consciousness, and cannot be traced further back, inasmuch as it declares itself by means of a direct consciousness."
